Infection by the staphylococcus bacteria are considered most amenable to treatment by vaccines as these bacteria have but feeble toxic powers upon the resident cells of the body; as they exert their influence most upon the red blood cells; and if we stimulate the formation of antibodies in the blood and cells of the body by injecting dead germs of the pathogenic organism, the invading germs are deprived of their cytolytic properties and the body forces are so increased that they can no longer exist.

Frequently we have a mixed infection caused by more than one kind of pathogenic organism operating in the same field at the same time, here a mixed vaccine is indicated to meet conditions in the special case.

While vaccines have yielded splendid results in select cases, they are by no means infallible and are regarded as auxiliaries to other measures of up-to-date medicine and surgery.

Serums are prepared from the liquid portions of the blood of animals, that have been treated with gradually increased doses of bacterial toxin or the attenuated killed cultures of the pathogenic organisms themselves.

The mode of preparation corresponds to the well-known law of Koch: 1st. There must be a preparation of toxin or the attenuated culture of the bacteria.

2nd. The toxin or culture must be injected into animal which renders the animal immune, the serum is taken from that animal and contains the antitoxin.

3rd. The serum thus obtained from the infected animal is now carefully prepared for use.

Serums are indicated when the condition of the patient is such that he can not supply his own antibodies to nullify the effects of the bacteria and its toxins. When it becomes necessary to supply them by means of serums which contain the antibodies thus conferring a passive immunity to the disease.

Serums are indicated in all general acute infections and have produced most brilliant results, as has been demonstrated in diphtheria and tetanus and many other infectious diseases. They are used for immunizing purposes; in this they are said to have the same effect as when administered for their therapeutic action; in that, they supply the necessary antibodies to the patient thus conferring for a time on active immunity to the disease. For their immunizing effects they should be administered as soon as possible after exposure to the disease.

The deleterious effects of bacteria may be

exerted in two ways: One secretes its poisonous substances into the blood serum, which are soluble and are diffused throughout the body and are responsible for the symptoms present in the disease; an example of which is seen in diphtheria in which about 90 per cent. of toxine is absorbed into the serum and 10 per cent. remains attached to the pathogenic organism in the form of endotoxine. In this class of infection an antitoxine is indicated to neutralize the toxine present. Another class of bacteria produce the poison within themselves and which remains attached to them; these are known as the endotoxic bacteria, an example of this class is seen in the streptococcus bacilli which produce 90 per cent. of endotoxine and only 10 per cent. of soluble exotoxine. In such cases it is readily seen that an antitoxine serum is of little use to combat the endotoxine, and the bacteria must be overcome by an antibacterial agent which destroys the bacteria themselves. In other words we must resort to active immunity in contradistinction to passive immunity acquired in such diseases as diphtheria.

As a summary to the study of vaccine and serum therapy, it is necessary to consider: 1st. What constitutes the elements of the body defense against the invading pathogenic bacteria.

2nd. To understand the nature of the invading bacteria and the effects of their secretions upon the fluids and tissues of the body.

3. To understand the therapeutic action of vaccines and serums; that vaccines act by stimulating the body to manufacture its own antibodies to defend itself from invading germs of disease; that serums supply the antibodies artificially when nature fails to do so.

4th. To understand that some bacteria produce toxins, while others secrete endotoxins and that we should carefully differentiate between one class and the other; so that we may apply the agent best suited to the individual case.

THE EARLY RECOGNITION OF TUBERCULOSIS.*

By J. O. MCKENNEY, Taylor Mines.

There is no disease where the early recognition counts for more than in pulmonary tuberculosis. From ten to fourteen per cent. of the mortality from all causes is due to tuberculosis, a higher percentage than is attributed to any other disease and from eighty to ninety per cent. of those who die could be saved if the cases had been recognized in its incipency.

It makes no difference how much we educate the laity in the prevention of tuberculosis,

if the physicians do not make a more thorough study of this disease and learn to recognize it in its earliest stages. Physicians should study tuberculosis more than any other condition since it causes a greater mortality. In making a diagnosis of tuberculosis we must first realize there is no combination of physical signs common to all cases—percussion and auscultation may be entirely negative. The contour, shape and size of the chest may not give any information and we may have only a small group of symptoms to guide us in our diagnosis. Yet by using everything within our power and grouping all the evidences, such as family history, personal history, predisposition, subjective symptoms and physical signs, we can usually make a diagnosis.

Some author divides the early cases of tuberculosis into three groups which will include most of the cases. The first group, a persistent slight cough with or without a little morning mucopurulent expectoration, with an afternoon temperature of 99 to 99.5. On examination there is usually found a slight high pitched percussion note in the supra-clavicular, infra-clavicular or upper inter-scapular region, and the apical outline is a little narrowed on the affected side. The breath sounds may be normal or harsh with prolonged expiration. A few fine rales are heard at the end of deep inspiration. Tubercle bacilli are not often found but in few cases repeated search may demonstrate them. With these symptoms and a positive tuberculin test you are able to make a diagnosis. The second group are patients complaining of feeling run down, their appetite has fallen off, they have indigestion, and sleep badly. They may have no cough or expectoration and no fever. They usually have lost some weight. The physical signs are generally like those of the first group. Sometimes the apices are normal but persistent rales on abdominal breathing are present in the fifth and sixth interspaces below the nipple or in the infra-axillary space. A wavy inspiratory murmur may be present. There is usually tenderness on pressure in the interspaces. The tuberculin tests have the same value as in the first group. In this group I would like to call special attention to a class of neurasthenias. There is no disease in which neurasthenia is as common as in tuberculosis. The tuberculosis poison has a powerful action on the nervous system and every variety of functional nervous system may result from it. Neurasthenia, therefore, should never be classed as such without a careful physical examination and daily temperature record and if the results are at all suspicious, a tuberculin test.

In the third group the onset is with a pleurisy; it may be dry or associated with an effusion; fever is usually present but may

*Read before the Ohio County Medical Society.

be absent; cough may or may not be present. The majority of these patients react to a tuberculin test; it is now generally conceded that spontaneous pleurisies are tuberculous in origin in most cases.

These three groups include the majority of early cases. Of course the disease may develop in many other ways, but these three might well be called basic groups. The two conditions which cause the most confusion in the early recognition of this disease are neurasthenia and influenza, but by careful examination, taking a daily temperature and using the tuberculin test we are able to differentiate.

The most important of the special aids to diagnosis are tuberculin tests. Of this test a great deal has been written for and against its value. But the weight of opinion inclines to the exceeding value of these tests. A positive result being strong evidence of the existence of tubercular infection in some portions of the body. The reaction is found to be more pronounced in recent cases and comparatively slight among the far-advanced. The tolerance among the latter suggest an effort of nature toward the establishment of an immunity.

There are three different tests that have been used. The subcutaneous, the cutaneous and ophthalmic, the subcutaneous and ophthalmic are being discarded on account of the possible danger that may attend their reaction. The cutaneous tests are called the Von Pirquet and Moro; the Von Pirquet test consists in making an abrasion through a drop of a 25 per cent. solution of Koch's Old Tuberculin previously placed upon the skin. The test is usually performed on the forearm for the sake of convenience. In event of positive reaction the area becomes red at the end of 12 hours; maximum hyperemia usually about the twenty-fourth hour but may be delayed from thirty-six to forty hours.

The Moro test consists of an ointment of 5 cc. of K. O. T. and 5 grams of lanolin base, a small portion of this being rubbed on the chest or abdomen over an area of four square inches. A positive result is characterized by a papular eruption over area of inoculation.

Febrile Tuberculosis and Tuberculin.—With a good tuberculin and proper care, seconded by some experience of the tuberculin treatment and incessant surveillance, Renon says the treatment of slightly febrile cases of tuberculosis (37.4 to 37.8 C.) may be undertaken without undue risk; but in general practice, to treat really febrile cases of the disease with tuberculin, without the requisite experience, is to expose the patients to serious dangers and possibly to create insurmountable obstacles to a successful treatment.

THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.*

By W. M. HYATT, Springfield.

Tuberculosis may effect any organ in the human body, but what I shall have to say will be directed to what we know as consumption of the lungs, a disease with which we are all familiar and which is, perhaps, more prevalent than any other form. In every age, and race and clime, in the old, the middle aged, and the young; in the mansions of the rich, in the homes of the great, middle class, and in the hovels of the poor; in the city, the hamlet, and in the country, we find the Great White Plague, the disease that causes one-seventh of the deaths of mankind. All over the world there is greater activity than ever before in organizing societies for the prevention and cure of tuberculosis and these are composed of both physicians and laymen. Governments are taking an active part in the movement and laboratories are being founded for the study of the disease, maintained by private and public munificence. Such a disease should command the attention and most careful study of every practicing physician. In perhaps no other disease is early diagnosis of so much importance. When well advanced the disease presents a picture so plain and unmistakable that even the laity readily recognize it. It is the incipient disease that we as physicians should recognize and what is said will be entirely confined to those signs and symptoms of the earliest stages.

The presence of the tubercle bacilli in the sputum is an infallible indication of the existence of tuberculosis, and since this means of arriving at diagnosis is within the reach of all we should use it early and often. Unfortunately negative findings are of comparative frequency. Many of the bacilli may not be stained at all; old foci may give off very few and recent foci no bacilli. By occlusion of a bronchus the contents of focus may be shut off entirely. They may be present one day and not again for months. It is best, if possible, to procure, the thick, lumpy portion of the sputum which is more apt to contain the bacilli. Since the State Laboratory is at our command, without cost, we should in any suspected case send several specimens to the laboratory.

In regard to tuberculin which is used both for diagnosis and treatment, it is generally admitted that the value of this agent in the obscure cases has become more and more firmly established, and its harmlessness, when properly used, has been proven by the results in many thousands of cases. Dr. G. Cornet, of Berlin, states "that the injections of tubercu-

*Read before the Washington County Medical Society.

lin often clear up the diagnosis in cases which baffle every other means at our command." It is generally admitted that Koch's old tuberculin is still the best preparation to be used. This agent should not be used in cases with high fever and so far as I know, it has not come into general use in this country among general practitioners. The danger from the use of the tuberculin test is slight, but in some unsuitable cases it is very real and possibly severe. After much experimenting the consensus of opinion seems to be that the subcutaneous test is the most trustworthy of the tuberculin tests. For the general practitioner, exposure to infection, characteristic symptoms such as fever, hemoptysis, pleurisy with effusion, dry pleurisy on both sides, and localized persistent physical signs at one apex are diagnostic data of far more importance in pulmonary phthisis than that derived from the tuberculin tests. The early symptoms of consumption are often obscure and misleading and we reach a correct diagnosis only after the patient's best chance is passed.

In the disease under discussion, particularly, it is not so much the things we know as the things we do that count for the relief and cure of those afflicted. The pessimistic attitude of the physician in regard to phthisis many times leads to neglect of the golden opportunity. The alert and active physician will be ever ready to apply all of his knowledge and to follow up every single sign and symptom presenting itself to him. It is our duty to prolong and save human life and nothing short of eternal vigilance constant, and earnest endeavor should satisfy the medical man.

In any suspected case we should get as complete history as possible, as to exposure, family history, occupation, environments and sanitary surroundings. The fact that the history gives no positive results does not in any way speak against the disease and we should therefore examine the patient by inspection, palpation, percussion and auscultation, these physical signs being as usual routine and always important, so they will respectively be briefly referred to.

By inspection in the early stages, we may find very little alteration of the external appearance. The patient may have every appearance of health and vigor and yet the bacilli may have been at work and have done considerable damage. Inspection is of no value without the patient's chest is bare or covered only with one garment. In many cases the characteristic deformity of the chest does not precede the disease but is rather the result of it, being due to the loss of the supporting tissue, especially the muscles and the fat.

Palpation generally confirms certain con-

clusions suggested by inspection. If both hands are placed on the thorax the diminution on the effected side becomes even more evident than by inspection.

Palpation also reveals an increase of fremitus when the patient is told to speak loudly. The important element is the difference between symmetrical areas on the two sides of the chest, and the more the process advances, the more marked do these phenomena become. "Disease at the apex, though early, and before dullness is at all marked, may be evidenced by deficient expansion." On asking the patient to count there is increased tactile fremitus whenever there is a local growth of tubercle or extensive caseation, but in comparing the apices it is important to bear in mind that normally the fremitus is stronger over the right than the left.

Percussion in the early stages of the disease very often fails to give definite knowledge. The effect of very small areas of consolidation upon the percussion note is counter balanced by the surrounding healthy portion of the lining tissue. In the early stages the percussion note is usually higher in pitch and may require an experienced ear to detect the difference. Authorities state that the individual tubercle requires two or three weeks for development, so it is easily seen that considerable time must elapse before a tuberculous focus can attain anything like the size necessary to become manifest through percussion. However, Osler states that "one of the earliest and most valuable signs is defective resonance upon and above a clavicle."

In auscultation we often have an early sign of great importance. The German authority, Dr. Cornet, says in his work that "the changes which occur in the auscultatory phenomena are second only in importance to the finding in the sputum."

Among the most characteristic early auscultatory signs are feeble breath sounds, the prolongation of the expiratory murmur and rales, the latter being most important and very often present before there is any changes in the respiration. "If rales are constantly found, even though in limited numbers, over one of the apices and at a fixed position, there can be scarcely a doubt of the diagnosis of tuberculous catarrh of the apex."

Under the local subjective symptoms there are cough, expectoration, pulmonary hemorrhage, dyspnea, hoarseness, dysphagia and pain.

Under the constitutional symptoms there are the blood, fever, circulatory apparatus, skin, sweating, alimentary tract, emaciation, urinary tract, and nervous and mental symptoms. It is not my purpose to discuss these symptoms in detail, first because of lack of time, and second because many of them are

unimportant in making a diagnosis in the incipient stage. While some of them, as cough, hemoptysis, fever, sweating, and hoarseness are often present early and their discussion would perhaps be of interest, there is only one of these symptoms that attention will be called to, and that is the fever, being according to my own observation and experience the most important early symptom in the diagnosis of consumption.

The great importance of this symptom warrants the utmost care in determining it, and since it requires no special training or skill there is no excuse for the physician to overlook it.

In speaking of the importance of this, as an initial symptom I wish to quote as follows: Osler says, "Fever is the most important initial symptom and throughout the entire course the thermometer is the most trustworthy guide as to the progress of the affection."

It was present in 100 consecutive cases in his dispensary practice. "In the early stage when tubercles are developing and caseous areas are in progress of formation and when softening is in progress, fever is a constant symptom."

Tyson says "fever is probably always present in the beginning—the fever of onset." Dr. Cornet says: "Closely connected with the absorption of poisons by the blood is the appearance of fever which outdoes all the other symptoms of phthisis in importance."

However, it must by no means be understood that every patient with consumption must have fever at all times throughout the course of the disease. While the initial fever follows no definite and constant type, as in other infectious diseases, the rise will most often occur between 2:00 and 6:00 p. m. It is very generally the rule in private practice, in institutions and in clinics to measure the temperature three times a day. Dr. Cornet states that "after fourteen years of observation directed to this point, I venture to state that in a large number of cases this does not register the temperature with sufficient accuracy." He has observed a great number of consumptives who had a range of temperature of 97.8 degrees at 8:00 a. m., 98.6 at 12:00 and 98.4 at 6:00 p. m., in other words, an apparently normal temperature, whereas a two hourly measurement showed a rise of 99.8 degrees and over at 3:00 p. m. This small rise may betray itself by a feeling of discomfort, or may run along for weeks unnoticed. It seems, therefore, far more reasonable and important to take more frequent measurements in order to detect the rise before it becomes pronounced and before the danger is already done. As the physician cannot take the temperature in person every two or three

hours, the patient must learn to do so himself and it is rare we find one unable to master the art. It is very often possible and even better to have some member of the family or nurse to attend to this and it is no doubt best to sometimes keep the patient ignorant of the true condition, but we cannot afford to sacrifice all our intelligent patients for the sake of those who develop an actual mania for the thermometer, and we certainly do sacrifice them unless we recognize the pyrexia in time. Our main object in taking the temperature is to find that there is a rise of temperature above the normal, the time of day that this occurs being of minor importance.

A temperature of 99.8 degrees to 100 degrees which is intermittent but obstinate and which increases on exertion indicates tuberculosis, aside from some other known condition or disease.

The books describe the different types of fever, the remittent, the intermittent fever with and without chills, and continuous fever, the fever of acute miliary tuberculosis but it is unnecessary to discuss these varieties as they are well known to all and these forms are usually accompanied with other symptoms which when taken altogether enable us to recognize the disease. There is no possible doubt that many of these early cases are overlooked, not from lack of knowledge, but from failure to apply and utilize it.

If we, as physicians, can know of one human being whose life has been prolonged for a year, or ten years, or perhaps restored to health, through our knowledge and efforts; if we by patient skill and watchful care in the sad hours of sickness, can cause the "rainbow of hope to shine through tears of grief" the dark pathway that leads to the temple of Esculapius will be lighted by the stars of gratitude and love and not far beyond the gate we may behold the Great Physician who will say to us "well done thou good and faithful servant." If we can destroy and dispel the countless hordes of deadly germs that lurk and live in millions of mankind we shall save more lives than all the shot and shell of all the world have killed.

We feel and know that the great clouds of lethargy hovering over the multitude of men afflicted with the Great White Plague, are lifting and the sunlight of hope and health is shining brighter and brighter and is dispelling the mists of doubt and dread.

TUBERCULAR PLEURISY.*

By A. D. WILLMORN, Louisville.

My reasons for reporting this case is not because of the rarity of it, but because of the frequency and the difficulty heretofore experienced in being able to relieve this class of unfortunate sufferers.

The following case will serve to illustrate a typical case also to illustrate what can be accomplished by the handling of such cases by a new method. Many of you no doubt have seen this treatment mentioned occasionally in your journals and those of you who were present in Paducah at the last meeting of the State Society will recall Dr. Murphy's mention of it in referring to conditions of the joints. It was a remembrance of this that prompted me to write Dr. Murphy asking the details regarding the treatment of the following case.

On January 26th of this year, I was asked by Dr. J. A. Flexner to see with him the following case: Miss H., white, age 27, ill since the 25th, who presented the following picture and gave the following history: Family history, parents living, one sister and two brothers living and in good health, one brother died of heart trouble, exact nature of which is not known. One sister died of tuberculosis some three years ago.

Personal history, five years ago this young lady had a severe attack of pneumonia involving the lower portion of left lung, from which she had a slow recovery and following which, at varying intervals, she would complain of severe pains in the side which she had been told was an intercostal neuralgia and for the relief of which the various neuralgia agents were used. On two or three occasions this pain was accompanied with a slight rise in temperature up to about 100 and the pain itself severe enough to confine her to her room for as much as one week.

On examination the following clinical symptoms were obtained: That beginning on January 25th, or three days previous she was taken with intense pain located near the mid-axillary line and radiating around in front, temperature rather steady and about 101 1-2, pulse from 100 to 120. Respirations about 25 to 30. Patient nervous, anxious expression and showed the effect of pain. Physical examination revealed an area of dullness beginning about one inch anterior to the mid-axillary line and extending nearly to the spine at the upper portion and beyond the spine in the lower portion, making a typical Green's triangle. This dullness extended from about the ninth rib up to about the third. Over this large area was increased vocal fre-

mitus. Almost a typical egophony could be heard over the entire area. No bulging of intercostal spaces could be elicited nor would changing of the position change to any appreciable extent the line of dullness.

We were both, however, firmly of the opinion that a fluid was present, (even though the pain had not entirely ceased) and had been forming for at least five or six days. To confirm the diagnosis and also to remove whatever we found in the pleural cavity I introduced under a cocaine anaesthesia a medium sized aspirating needle which was attached to the ordinary 3 ounce aspirating syringe. The puncture was made about three inches posterior to the axillary line and between the sixth and seventh rib. We were rewarded for our efforts by the withdrawal of 10 1-2 ounces of straw-colored fluid.

This relieved the breathing and made the patient much more comfortable and reduced the temperature down to 100 for the next three days.

There could be no question but what this was a case of tubercular involvement of the pleura with little or no involvement of the lung tissue proper since there was no cough except the short hacking due to temperature.

It was at this time that I communicated with Dr. Murphy to know if he was still as enthusiastic over the injection of the formalin solution as he was in October. He informed me that he was and that if I had occasion to use it to use 4 drachms of a 2 per cent. solution in glycerine. Inject this in the pleural cavity after withdrawing all the fluid I could wait ten days aspirate again if the fluid came away clear reinject, if it was blood, leave it alone.

Four days had now elapsed since my first aspiration and the patient's temperature was now going up to 102 1-2 each afternoon but the physical signs did not warrant another aspiration. Six days later, however, we had all the signs of a re-accumulation with a temperature of 102 1-2 and a pulse of 120. Under a local anaesthesia I again aspirated and removed twenty-four ounces of the same character of fluid as before; after removing all the fluid I could I injected through the same needle 1 drachm of a 2 per cent. solution of formalin in glycerine, which I had had prepared twenty-four hours previous and had it shaken frequently to be sure it was thoroughly mixed. The injection gave intense pain, feeling as though hot steam had been forced into the cavity, requiring a small dose of morphine to give relief. This was about 11 a. m. at 5 p. m. I saw this case again and to say that I had gotten a reaction would be putting it mildly, respiration about 30, pulse 120 to 130 and the temperature 104. With an abiding faith in the one who had advised this and

*Read before the Muldraugh Hill Medical Society.

with a patient whose confidence was not to be shaken, I felt all would eventually end well. This temperature continued for five days but the local condition in the side was plainly getting better. After five days the temperature stair-stepped down to the normal, requiring about two weeks for it to reach the normal both morning and evening. This patient was in bed six weeks and three days and weighed when she was able to get up about 100 pounds. She now weighs 116 1-2 and is steadily gaining and has every appearance of being on the road to a complete recovery. At the end of three weeks, at the time the injection was made, the normal breath sounds could be heard over the entire area. In other words it had cleared up.

I am indebted to Dr. Flexner for the privilege of reporting this case, also for his valuable suggestions in regard to the diagnosis and to the management of this case as regards the medical aspect.

I regard this as a complete cessation of symptoms due to treatment. In other words, I regard it as one of my best results and I commend the treatment to you.

DIAGNOSIS OF INCIPIENT PULMONARY TUBERCULOSIS.*

By EVERETT MORRIS, Sulphur.

There is no disease so prevalent as tuberculosis and none that needs a diagnosis so early. This widespread distribution can best be reduced by education. "Consumption" should be written on the door plate of every American home, instead of in the family Bible under "Deaths." The emblem of this disease should decorate the stained windows of every church and "tuberculosis" should be the one word into all ill ventilated buildings. Peace conferences and arbitrations are commendable but the great destroyer of man is not the battlefield but the "bugs". It is important to teach in your kindergartens, by charts and pictures, all that can be understood about tuberculosis. In your public and high schools teach from text books and in your colleges and universities establish a lecture course on public hygiene. It is also necessary to prevent public opinion from swinging to the other extreme, viz.: phthisiophobia. This can easily be avoided by teaching the harmlessness of a careful person suffering from tuberculosis.

Tuberculosis is communicable; then it is preventable, and if preventable, it is curable; this proposition necessarily places the burden on preventive medicine. Since tuberculosis is not, as a rule, congenital it is within the province of preventive medicine to forestall any

implantation in a child living in unhygienic surroundings. Infection in children under three years usually overwhelms them; but if they survive they will, in all probability, when adults, realize the latency is no longer latent. The theoretically speculative assertion of Hamburger, that latent tubercular infection in childhood produces a certain degree of immunity against secondary tuberculosis, offers poor comfort.

Martha Woolstein, of the New York Babies' Hospital, analyzed at autopsies 1131 children under three years and found 16.4 per cent. tubercular. Albrecht, of Vienna, discovered 16.6 per cent. infected in 1300 post-mortems held on children under one year. It is interesting to note the uniformity in results these pathologists reached. It is also shown that as children reach puberty the rate of tuberculosis increases proportionately.

Muller in 500 autopsies on children under fifteen years, found 42 per cent with evidences of infection, while Albrecht found 50.1 per cent. in 355 under twelve years. These figures force us to ask, why not put tuberculosis in the category commonly called children's diseases? These statistics are recited to call your attention especially to early tubercular infection as regards the phthisiogenesis of adult life. Andvord believes 75 per cent. of adults suffering from tuberculosis acquired it primarily during childhood. It is a long call between seed-sowing and harvest.

DIAGNOSIS.

We prefer the word tuberculosis to phthisis since the latter means a wasting away. The condition that we want to describe is without any appreciable wasting away. If we should wait until the word "consumption" were applicable it would require no special skill to make a diagnosis and no therapeutic agent would ameliorate the condition. We must then, as progressive medical men, learn to discover this disease early and look for arrested cases, apparent cures and cures in a direct proportion to the promptness with which we make our diagnosis. An early diagnosis is not easily attained but any one of us can reach that degree of proficiency necessary if we are willing to work hard on every case that looks suspicious.

SYMPTOMS.

The earliest subjective symptoms manifest themselves in many ways and are interpreted by the laity as inconsequential. For this reason a physician does not have the opportunity in most cases, to make an early examination. Occasionally the disease reaches the second stage before any symptoms appear. Among the earliest symptoms noticed by patients is lassitude. An energetic business man will find

*Read before the Henry County Medical Society.

his usual labors a great tax on his strength but attributes it to hard work. A seventeen-year-old school girl (whose neck and upper chest are exposed to the cold of winter and whose feet and legs enjoy the fastidious silk stockings) comes to your office with a "tickling in her throat and a stitch in her side" blissfully ignorant of the fact that 90 per cent. of pleuritis are tubercular. An elevation of temperature is one of the most trustworthy symptoms as to diagnosis and important as to prognosis. This serves as a warning of the enemies' activities. Any reading between 97.8 degrees F. and 98.8 degrees F., is considered normal, a subnormal waking temperature with an elevation during the day, without a known cause is suspicious, a thermometer should be used by the patient immediately after waking, at 10 a. m., 4 p. m., 8 p. m., and never until one hour after taking nourishment, a correct record of these readings, together with the pulse taken at the same hours, should be kept while patient is under observation. Slight chilly sensations followed by fever often resembling malaria is not uncommon. Afebrile cases may baffle the best clinicians until positive evidences are discovered. Tachycardia is a very early symptom in this disease. The pulse rate, however, is usually below 110 when the patient first consults a physician. The pulse rate is the best prognostic sign we have.

Anorexia with slight or no loss in weight is quite possible.

Contrary to its insidiousness early tuberculosis sometimes manifests itself under the pseudonym "bronchitis." Any cough with the usual attending symptoms lasting longer than one month should be carefully considered.

Perhaps the first symptom to cause any alarm on the part of the average layman is hemoptysis, this is very suggestive but is must be remembered that 20 per cent. of hemorrhages are not tubercular in origin.

As to expectoration it is usually swallowed. Since many cases are closed and a large number of open cases do not expel tubercle bacilli until late, we should not wait for a microscopic examination before making a diagnosis.

Family history is negative unless two or three generations have had several cases of tuberculosis. Too much importance has been given to family history and not enough to primary infection during childhood. Previous occupation and diseases, present environments and habits are also worth investigating.

PHYSICAL EXAMINATION.—EQUIPMENT.

It is preferable to make the physical examination at our office before the routine morning office work begins, the patient will be refreshed, the roles more audible and the physi-

cian's faculties keener. With a room temperature of 75 degrees F., request patient to disrobe to the waist (examiner, of course withdrawing, if a female).

Place patient on a comfortable upholstered revolving stool facing a large window and on a similar stool seat yourself facing patient with back to light. At your right have a table one yard square on which have a record sheet (ten by fifteen inches) large enough for erytometer tracings and all other data so necessary in subsequent examinations; here keep your erytometer (lead tape 1-8x5-8x24 inches and covered with soft leather), stethoscope, calipers (for antero-posterior diameter of chest), skin pencils (for making landmarks, etc.) and a table of normals weights according to height. Both patient and examiner should be comfortable and no interruption during the examination should occur. By using tact we can soon overcome the uneasiness so often seen in women and gain their confidence. In most cases I believe it is proper to tell the patient frankly several days before the examination is made just what the possibilities are.

SIGNS.—INSPECTION.

A shoulder droop with a corresponding lagging in excursions on deep inspirations on the same side is suggestive. Any deformity of the chest should be inquired into and a well-formed thorax with a slightly marked bulging of the clavicle or flattening of the supra or infra clavicular fossae should not receive a perfunctory examination. The shape of the chest, the width of the intercostal spaces, the size of the substernal angle, complexion, teeth, nutrition, evidences of dyspnoea and scoliosis all add to the grand total—"T. B. or not to be."

Inspection of the naso-pharynx, pharynx, and larynx is important. Any obstruction in the upper respiratory tract favors tuberculosis.

PALPATION.

In the early stage this method of examination is of little diagnostic value.

MENSURATION.

In the normal chest the circumference over the spine of the eighth dorsal vertebra and a mid-sternum point opposite the fourth rib should be one-half the height. These landmarks should be marked with a skin pencil. To determine any limitation in motion measure the halves separately. The calipers placed on land marks will give the antero-posterior diameter, while the erytometer will give graphic tracings which will show any asymmetry. With the chest in repose place one end of the erytometer on the posterior landmark and mould around one side to the anterior landmark, especial care being necessary in the axilla. Mark on tape over the ax-

terior landmark and turn free end slightly back, carefully remove without spreading, then place the posterior end and the marked point at the ends of the diameter already recorded by the calipers and follow the concavity with a skin pencil. Do the other side as the first, then place it over the first and with a different colored pencil run around the inside of tape. This will show very clearly any asymmetry. Due allowance must be made, however, for being right or left handed. Then tracings are extremely helpful in later examinations, but it takes practice to be able to make them correctly. All subsequent examinations should be made on original record sheet, but with a different colored pencil.

This valuable agent has been neglected but is now being popularized by C. L. Minor, of Asheville.

PERCUSSION.

This is one of the most difficult methods of physical examinations to master since the physician has to produce the note and then interpret its meaning. As one gets an idea of pulmonary resistance only by using a finger for the pleximeter as well as one for striking this method is preferable. The three essentials for perfect technic are: the use of only the finger and wrist joints, a vertical stroke of the percussion finger and an immediate recoil. It is imperative to percuss lightly especially over apex in front. Over thick muscles and much fat percussion is well-nigh useless. It is important first to outline and mark with a skin pencil the apices and bases. The latter should be done during shallow, and at the end of deep breathing, as this will give an idea of the utility of the bases. It is to be remembered that the field of resonance between the internal and external lines is much larger than the true anatomical apex; but diminishes in the same proportion as the apex shrinks from functional inactivity.

To outline the apex begin to percuss well up on the neck, coming straight down to pulmonary resonance (dot with skin pencil). Carefully work forward until six or eight dots one inch apart have been made. Connect these and the result will show the anterior inner line with a slight outward convexity above and a slight inward convexity below. For locating the outer line, begin near the shoulder and work in the same manner towards the neck. This line will be shorter with the convexity inward. The posterior lines should be mapped out in the same way. The next step is to percuss this area for any abnormalities. We cannot expect to find in incipient pulmonary tuberculosis any distinct changes, as marked dullness or flatness, since a deposit of scattered tubercles surrounded by normal lung tissue furnish the cause for any irregularity in the percussion note. This is

described as a slight "shortness" of note; the duration being less and slightly elevated in pitch. There may be, however, the slightest dullness or any impaired resonance or hyper-resonance, the latter being very misleading. If both apices are not involved a comparison of the two is extremely helpful. It is worth remembering that the normal apex furnishes slight dullness near the shoulder, slight tympany near the trachea and only a clear note between the two. There is some difference of opinion among authorities as to which fossa is the commonest site in apical dullness. Fluoroscopic findings show in most early cases, the inner part of the supraclavicular fossa and the inner third of the infraclavicular fossa are oftenest involved. The entire pulmonary area should be interrogated as thoroughly as the apices. As the examination proceeds all symptoms and signs should be noted on record sheet.

AUSCULTATION

The technic in auscultation is simpler but much more important than percussion. Whether one uses a stethoscope or not is a matter of choice. Personally, I prefer one as it eliminates all strained positions, intensifies faint sounds and reaches areas otherwise inaccessible. To get best results always use same instrument.

As many people make a noise in their nose while breathing, it is well to correct this before auscultating. Let patient's arms hang by sides and relieve any strain thus avoiding muscular friction sounds. Shivering will also produce these false sounds. To eliminate friction sounds caused by hair or rough scaly skin under stethoscope use a little oil.

The earliest apical changes are told best by auscultation. Only the supra and infraclavicular fossae; interscapular and supraspinous regions may be expected to reveal the secret. This is done first by changes in normal breathing and later by more reliable diagnostic signs—rales. The latter are not, however, essential if the former are corroborated by other positive evidences.

The first sound to differ with the normal vesicular murmur is called "rough or granular respiration" and is described by Turban as a series of short, quick recurring sounds and depends on their rapidity and strength whether the ear can differentiate them, from rales or not."

Cassart writes: "The air seems to be constantly passing over slightly elevated obstacles by which it is constantly broken and this sensation of obstructed progress gives the idea of a rough inpolished surface." Minor described this respiratory change "As rough and low-pitched, and is made up of a succession of very short sounds, as though small,

soft granules of fine, wet sage were being rolled over each other."

Granular breathing, largely inspiratory, is due according to Turban to a rapidly interrupted entry of air into the alveoli surrounding the tuberculous deposit.

A decided lessening in intensity of both the inspiratory and expiratory murmur is called "feeble breathing"; and is usually the second abnormal breath sound heard in early tuberculosis. This can be produced by as many other causes other than tubercularization that to be of diagnostic value it must be permanent after cough and located above the clavicle.

"Wavy," "interrupted," cog-wheel or jerky" breathing is described as having short expiratory and inspiratory pauses during which time the air is held and then released. This variety of respiration is best heard during quiet breathing and is usually posterior.

It is due according to Sahli to the valve-like action of the swollen mucous membrane. Another form of breathing found in the majority of cases towards the end of incipency is "harsh respiration." The normal vesicular murmur is replaced by sharp blowing sounds heard chiefly on expiration. When heard during quiet breathing and over an apex it indicates a narrowing of the bronchi and condensation. Strictly speaking it should not be classed as an early sign. It is said to be normally found in the right apex.

There is no arbitrary rule as to the order in which these abnormal sounds are heard.

Heart sounds unduly transmitted over the right apex are considered of diagnostic value.

Adventitious sounds in the earliest stage of pulmonary tuberculosis are absent. A few small, dry, crackles (not dissimilar to those heard in beginning pneumonia) found in an apex, and remaining after coughing or returning very soon, furnish splendid evidence of localized deposits. They can be made more audible by the use of ipecac or potassium iodide. Deep breathing followed by a cough, or visa-versa, will often produce them. Lawson Brown says: "If heard on quiet breathing the case is no longer incipient."

It is manifestly impossible to differentiate true rales from false pleuritic friction sounds.

Most of us will find blood examinations impracticable but, tuberculin a valuable adjunct.

It is not just to either the physician or the patient to dismiss a suspicious case after only one examination. No positive diagnosis can be made on anyone physical sign alone, as any sign can be produced from another cause; but a conclusion based on the sum total of all the signs, symptoms and histories will warrant the diagnosis of early tuberculosis.

ADDENDA:—For much that has been presented on signs, I am indebted to Dr. Charles

L. Minor, of Asheville, N. C., with whom I have had the pleasure to be closely associated in tubercular work.

INFLUENZA, OR LA GRIPPE.*

By T. H. HARDESTY, Paynesville.

The name influenza is derived from the Italian term *influentia*, meaning in that language, a mysterious influence, supposed to be exercised by the stars, and while this disease is very accurately described during the last three centuries it remained for Pfeiffer to discover the true cause, a germ now known by his name. It originates in the east and travels in a western direction extending over more country and affecting a larger number of persons at the same time than any other disease, no part of the civilized world being exempt. Whole crews on ships at sea have been attacked at one time as in the epidemic of 1782 which went rapidly from one country to another when the crew of one vessel commanded by Admiral Kempenfelt had to return to England from the coast of France, not having able men enough to run the vessel.

It is an acute contagious disease, its chief symptoms being due to catarrh of the respiratory and digestive tracts, together with profound muscular and nervous prostration and grave complications often present themselves.

There is no special anatomical lesions that characterize this disease. When death does occur in an uncomplicated case, which happens very rarely, the catarrhal changes in the respiratory and gastro-intestinal mucosa disappear after death. In the abdominal type there may be enlargement of Peyer's patches and solitary follicles. Among the fatal complications are pneumonia (mostly lobular), pleurisy, empyema, endocarditis, and rarely meningitis.

There is still doubt as to the manner of invasion, but most people believe the contagium enters by the respiratory tract; still there are others that believe it enters via the alimentary canal and rarely by conjunctiva.

While all persons are liable to contract this disease the very young are least liable, and the very old are the greatest sufferers, and those of any age whose vitality is lowered by hereditary disease or other chronic maladies. It is fortunately one attack does not grant immunity, since relapses are very common.

The incubation period is brief, rarely extending over two or three days. The onset is sudden, either with a severe chill or repeated shiverings followed by a rapid rise in temperature, which may reach 104 or 105 degrees F. accompanied by a severe headache, generally frontal, sometimes temporal, or occipital, de-

*Read before the Meade County Medical Society.

pressing myalgic pains with great prostration. The primary fever varies greatly, as does the other symptoms both local and general.

Prostration, restlessness, depression of spirits, insomnia and sometimes mild delirium constitutes the most common of the nervous symptoms. It may begin with vertigo, vomiting, by abrupt and profound prostration, and sometimes by nose bleeding.

But the most common symptom is pain, which, as before stated, is in many cases referable to forehead, temples, root of nose and eyeballs, accompanied by general muscular pains starting, in a number of cases, in the lumbar region, sometimes taking the form of a neuralgia of individual nerves, or pleuritic stitches and boring muscular pains, temperature curve is irregular, terminating in a few cases by crisis. Pulse irregular, feeble, sometimes intermittent and sometimes unusually slow, the depressing effects of the poison reaches a dangerous degree.

Dyspnoea is met with frequently, which I believe is due to oedema of the lung, although it may happen independently of lung complications; sweating may be a troublesome symptom.

We have several types of la grippe described. The difference being due to local manifestations and varying degrees of toxemia.

Respiratory type, beginning with the local catarrhal symptoms, which develop in one or two days, as shown, first suffusion of the conjunctiva, excessive lachrymation, frequent sneezing and slight sore throat, a little later hoarseness and cough comes on, which is hard and dry, the cough and other local symptoms are due to an intense dry condition of throat and tracheal irritation; in most cases the expectoration is scanty.

In a small proportion of cases there is considerable expectoration and physical signs of ordinary bronchitis are present.

Other cases appear to present more of a gastric or gastrointestinal disturbance. The catarrhal symptoms here center in the digestive system most frequently in children; in such there is vomiting, which comes on early and is repeated at short intervals. There is diarrhoea, more or less urgent, severe abdominal pains as a rule, also cardiac group of symptoms accompanied with heart failure and distress with rapid, feeble pulse, also nervous or typhoid, which presents a continued fever; a rheumatic type which is known by violent pains in the muscles all over the body.

The complications most commonly met with are, bronchitis, affecting capillary tubes and leading to lobular pneumonia; we also find congestion associated with oedema of the lung, occurring as a complication. We also find lobar pneumonia as a complication and which may prove fatal; it is more likely to be

found after influenza toxemia has spent its force and when it does arise is ushered in by same train of symptoms of invasion, viz.: severe chill, high temperature followed by the usual physical symptoms.

We also find pleurisy, particularly in cases of lobular or lobar pneumonia; other forms are found though not common.

I have had two cases in the last three years followed by empyema, both recovered, but only after months of convalescence. I have found the most common complication to be nephritis, and while it may escape our attention, I don't believe there is hardly a case of influenza of a severe type where, if you will question closely, you will find that there is always scanty and high colored urine at some stage of the disease, and more cases of chronic kidney disease brought on by this than any other disease.

Diagnosis of this disease is usually made without difficulty except in sporadic cases. The number of people attacked at one time, sudden attack alternating flashes of heat and chilliness, fever, headache, sore eyeballs, myalgia and prostration out of proportion to the catarrhal manifestations form a picture which none of us should mistake.

SEQUELA.

Among these could be mentioned chronic bronchitis, phthisis, and abscess already referred to, chronic nephritis, cystitis. Otitis is a common sequela and should receive special treatment, mastoid abscess is mentioned, but I have never met a case I could trace to influenza.

Prognosis on the whole is good, almost all fatalities are due to complications, except in the very old or those already run down with some chronic malady.

The mortality is low, less than 1 per cent., sometimes less than 1-4 of 1 per cent. while in other epidemics it reaches 2 per cent. Its duration is brief in uncomplicated cases, runs from 2 to 5 days, in severe cases from 7 to 12 days, but convalescence is usually protracted.

TREATMENT.

As far as possible, particularly those at extreme of life, should, during an epidemic, be protected by proper wearing apparel and also should not be exposed to unfavorable weather conditions.

After the attack has set in all should remain indoors and if much prostration, should remain in bed until convalescence has set in. In mild cases, usually 2 to 5 days, in severe cases longer or until convalescence is well established.

The diet should be light and nutritious, milk, eggs, rice, vegetables and stewed fruits, cooling drinks, lemonade, effervescent mineral

waters. Bowels should be moved regularly, but avoiding active purgation. Where depression exists I use stimulants, light wines, or brandy toddies. In all cases even the mildest, I prescribe moderate doses of quinine, from three to four grains four times daily; for the headache and pains I combine with it Dover's powder and monobromated camphor, repeated every three or four hours, and for the languor and debility I use strychnia until in robust persons, I reach the 30th grain, beginning with the 60th. I also give calomel in small doses on the first day until three or four doses of one grain each are given.

If the myalgia and headache is not relieved by the Dover's powder, quinine and monobromated camphor I give morphine in small doses and sometimes give it hypodermically, if not relieved readily by the mouth.

In case of sleeplessness a hypnotic may be needed as sulphonal, acetanilid or opium, but do not give the coal tar group often in these cases, owing to the depression already existing.

For the coryza and bronchial irritation, steam inhalations, and for the dry cough attending the latter condition, I sometimes give codeine with syrup of wild cherry 2z chloride of ammonia, tablespoonful every three or four hours. Chest pains are sometimes relieved by the use of turpentine stupes.

Sudden cardiac failure should be met with the frøer use of strychnia, camphor and digitalis. I like the infusion the best in tablespoonful doses repeated every three or four hours; in extreme cases nitroglycerin and aromatic spirits of ammonia and carbonate of ammonia.

As one attack does not render us immune from another, when convalescence sets in the greatest care should be exercised in not allowing patients to go out too early, the temperature at this time in a majority of cases is subnormal, due to the weakened condition of patient and is, therefore, very susceptible to a chill on this account. I do not like to allow patient to be exposed to external atmospheric conditions. Therefore keep them in the house a more liberal supply of food and tonics, gentian, iron, quinine and strychnine or the hematic syrup of the hypophosphates until recovery is complete.

Atrophy of the Lungs.—In the case reported by Bauer the patient was admitted to a sanatorium with the diagnosis of pulmonary tuberculosis, but she proved to be free apparently from this, and the abnormal findings were the result of a partial lack of development of the lung or, as he styles it, atrophy of the lung on a basis of inherited syphilis. The Wassermann reaction was positive in the serum and the albumin reaction in the scanty sputum.

LOBAR PNEUMONIA.*

By C. T. Riggs, Upton.

I have sought to take up only frank lobar pneumonia, as to deal with atypical types would make a paper of this nature too long.

Lobar pneumonia, pneumonitis, croupous pneumonia, fibrinous pneumonia, true pneumonia.

DEFINITION.

An acute infectious disease characterized by inflammation of the lungs, chill, high fever and fibrinous exudate, usually terminating in crisis in from three to five days.

HISTORICAL.

What we know as lobar pneumonia was, no doubt, known to the earlier medical writers. Hippocrates describing it as peripneumonia or pleuritis. But it remained for Laennec, 1819, to separate the two diseases, and classify pneumonia into the three well-known stages which hold to-day—congestion, hepatization and resolution or suppuration.

ETIOLOGY.

Predisposing causes, overwork, previous attack, fatigue of body or mind, exposure to cold and dampness, overcrowding in poor ventilated rooms, lowered vitality from any cause, as previous or present illness, such as a chronic Bright's disease, etc.

EXCITING CAUSE.

The diplococcus of Frankel. It occurs in pairs or rows and is pointed at one end, hence the name bacillus lanceolatus, lanceol shaped. Its mode of entrance is most likely through the air passages since it has been found in those parts, and is said to live for months or even years in the saliva of healthy persons who have had pneumonia.

The pneumococcus of Friedlander is found in about five per cent. of all cases and was formerly thought to cause pneumonia, but the opinion at present is that Friedlander's bacillus is not pathogenic, but is a harmless saprophyte.

MORBID ANATOMY.

In lobar pneumonia, the lung presents three different stages: congestion or engorgement, red hepatization and gray hepatization.

The seat of election in pneumonia seems to be in the lower lobes of the lungs, and in the right oftener than the left.

THE STAGE OF CONGESTION.

In this stage the lung is very much engorged, blood transudes into the air-cells and, also, may be found exfoliated alveolar cells, this part of the lung is a great deal heavier and

*Read before the Muldraugh Hill Medical Society.

redder than the normal lung, yet air permeates the vesicles.

The second stage or stage of red hepatization. In this the lung is dark red and is as much as three or four times as heavy as in health. A piece dropped in water sinks at once; on section, it very much resembles the liver, hence the term hepatization.

The third stage or stage of gray hepatization. This is also well named as on section it shows a grayish-white color, is still heavy, but more moist and softer. It sometimes happens that all three stages are seen alongside each other. There is also a fourth stage sometimes spoken of as yellow hepatization, but this seems to be only the latter part of the third stage or the beginning of resolution in this the contents of the air-cells liquify, this partly being expectorated, the lower part being absorbed.

The pleura just over the affected part is most always inflamed as is shown by the plastic deposit, and intense pain on coughing. There may be also a thickening of the pleura and a serous deposit.

SYMPTOMS.

There is possibly no other disease, except perhaps malaria, that is so certainly preceded by a chill, as is pneumonia and is usually very severe. The patient usually presents the following picture and history: After exposure to cold or dampness, he may or may not have prodromal discomfort with headache, which may be severe. Suddenly seized with a chill, which may come on at night, followed almost immediately with high fever, 105 degrees, with a flush on both cheeks, usually more marked on the affected side, pulse full and bounding, rate 100 to 120, thirst and the urine scanty and high colored, pain in the side, which depends on its severity to the amount of pleura involved. The breathing is short and rapid, the cough is dry and hard and is often restrained on account of the pain it gives.

In twenty-four to forty-eight hours the sputum begins to show distinct characteristics, tough, light red in hue, "rusty" and is gotten out of the mouth with difficulty. At other times the sputum may be thin and dark, "prune-juice."

The appearance of the patient is very striking, face flushed, eyes brilliant, breathing rapid, the alae nasi dilate, and a frequent short cough held back as long as possible on account of the pain it occasions, the patient lies upon the affected side, not only to lessen the pain by the pressure, but to lessen the dyspnoea by giving more freedom to the unaffected side. This is about what inspection would disclose.

Palpation would reveal vocal fremitus di-

minished at first, but will become decidedly increased as the air vesicles fill up. The skin is hot and dry, the pulse is frequent, full and strong.

Percussion gives absolute dullness over the affected part, but may have exaggerated resonance over the adjacent normal lung, perhaps not so much, from supplemental function as from relaxation of the air vesicles, Skoda's resonance.

We can detect, with the ear over the solidified area, high bronchial breathing. The ausculted voice gives bronchophony and sometimes pectoriloquy. The heart sounds are more distinct over the consolidated area owing to the improved conduction.

The state of affairs as described above exist for from three to nine days, if resolution takes place, we have a sudden drop in temperature, followed by heavy perspiration and a state of ease succeeds one of great distress, often to be followed by a long refreshing sleep. This is known as the crisis. From this time on convalescence is steady and rapid, and in a few days the temperature and pulse are normal; however, the patient is weak and demands care for a time longer. When the pneumonia terminates unfavorably we have one of the following conditions: cardiac failure, abscess, gangrene of the lung, or phthisis pulmonis.

DIAGNOSIS.

The diagnosis of pneumonia is usually easy, exposure followed by chill, high fever, rapid pulse and short, suppressed cough, tells the tale.

PROGNOSIS.

There are many things to be reckoned with in making a prognosis. The young and robust, nearly all recover, while the old and debilitated nearly all die; but the mortality should not exceed 15 to 20 per cent.

TREATMENT.

There is no iron-clad rule that we may follow in the treatment of pneumonia, but each case is more or less a law unto itself. The following treatment is about the routine that I institute in uncomplicated cases:

Put the patient in as comfortable a room and position as possible with plenty of ventilation, but no draught. Place a hot poultice over the affected side; I prefer a plaster of antiphlogistine, covering the entire side, then a batten jacket over this. If seen on the first day, I give a brisk calomel purge, followed by oil if needed. Of course, the treatment varies with the age and vigor of the patient, but if the patient is a vigorous adult and seen on the first day after the initial chill, I give from 20 to 25 grains of quinine and urea hydrochloride hypodermatically, then 15 to 20

grains every three or four hours for the first 24 to 48 hours. This can be given by the mouth, but I like it better hypodermatically for the first day or two, then it can be given per oris in 10 to 15 grain doses, every three or four hours, being governed by the temperature. If this is not sufficient to control the fever, light sponging of the forehead and face, or a moist cloth applied to forehead might be tried. A little alcohol, in the form of whiskey or brandy, may be given in milk every three to four hours. Dover's powder in sufficient dosage to control pain and induce sleep may be given.

As an expectorant and diffusible stimulant, carbonate of ammonia should be given in small doses oft repeated. Liquid nourishing diet should be maintained until convalescence is well established. Inhalation of oxygen may be given for the relief of dyspnoea. To reduce the fever and relieve delirium, small amounts of a normal salt solution may be thrown into lower bowel frequently.

I have intentionally left off the serum and vaccine treatment as I have had no experience with them.

SKIN CONSUMPTION.*

By D. C. DONAN, Three Springs.

Synonym—Struma Derma, Scrofulous Tetter, Misnomer Pellagra.

My first case was Matt Thompson, an uncle of Dr. C. J. Walton. He came to me for advice when I first began practice in 1859. He then lived at the Raccoon Spring, Hart county, near Hardyville. I told him it was a strumous disease and that alteratives, sarsaparilla, etc., were the main remedies. He would sometimes come into the office, take up the laudanum bottle and drink it like whiskey, which he said allayed or soothed the itching face.

My second case was that of C. C. South, of Center, Metcalfe county, Ky. His face, hands and arms peeled off leaving a red delicate surface. Iodine and campho-phenique were recommended which healed the disease for a time, but he had at the same time tubercular phthisis of which he died in a year or two.

My third case was Jack Harding, of Liletown, Green county Ky. He had lung consumption and skin consumption at the same time. I prescribed for him iodo-bromide of calcium compound for the skin disease and the phosphates of iodine, quinine and strychnia for lungs. He was unable to prevent

them and finally died of consumption of skin and lungs.

STRUMA OR TUBERCULOSIS.

My fourth case is Dan Gupton, of Greensburg, Green county, Ky., a hotel keeper. I prescribed for him the iodo-bromide of calcium, three times daily, and to sponge himself all over every night at bedtime with a wash of lime water, sulphate of zinc, boric acid and sulphur, to stop the tormenting itching which deprived him of sleep nearly the whole night and which was fast making him a mental wreck.

A brother died of consumption.

STRUMA OR TUBERCULOSIS.

My fifth case was that of Miss S., of Edmonston, Ky. I was consulted by her half brother some years ago about her disease. Struma derma, which had spread entirely over her face, making it red and rough with a continuous tormenting itching. I prescribed resinol for the itching, but she said she had tried it without much, if any, benefit. I also advised alteratives.

She had a brother who had a tuberculous cough for two or three winters before he was killed in Louisville.

This article is written to ridicule the idea that corn meal will produce pellagra or skin consumption. It only shows how seemingly wise men can be in error. If corn produces any disease at all it is from the ergot which is shelled off the ear with the sound grain—this ergot is on the little end of the ear of corn and sometimes prevents cows conceiving while being corn-fed, and if given to chicken cocks it will rot their combs off from dry gangrene.

CANCER.*

By N. W. MOORE, Cynthia.

To me, one of the greatest problems of the future for the medical profession to solve, is cancer. We have removed the veil from many of our most dreaded diseases, such as tuberculosis, typhoid fever, diphtheria, malaria, yellow fever and syphilis, but the origin and cure of cancer remains, plunged in the darkness of ignorance, and a vast unexplored wilderness lies before us.

A disease that is rapidly on the increase. A disease, that when we inform our patient of his condition almost invariably abandons all hope of recovery, and looks forward to a life of long suffering—we stand so helpless in its presence, when the disease is fully developed, that we almost abandon him to his fate, and feel relieved when the end comes, and yet in

*Read before the Metcalfe County Medical Society.

*Read before the Harrison County Medical Society and the Bourbon County Medical Society.

the light of our present knowledge of this disease, we are longing and hoping for another Ehrlich who will rise up and show us how to conquer one of the most terrible of human diseases.

What is cancer? Is it a germ so small, that our most powerful microscopes fail to detect? Is it due to an excess of meat eating? Is it due to an over-indulgence in alcohol? Is it due to an excess of salt in our food? Or is it of a nervous origin? All of these theories have been advanced by some of our best men, and have been disproved by scientific investigation.

The discovery that malignant tumors exist in the lower animal both in their wild and domestic state has awakened new theories, also the experiments of transplanting carcinomatous tissue from one mouse to another until whole colonies have been infected; however this is what is called mouse cancer. There is no authentic case of inoculation of the human being either from man to animal or man to man.

In 1901 Dr. Senn voluntarily endeavored to inoculate himself with cancer, by imbedding a section of cancerous tissue in his forearm, but no serious results followed. He also took carcinomatous tissue from the leg of a patient and implanted it in various parts of the affected limb with negative results.

One of the greatest proofs it seems to me that cancer is not due to micro-organisms, is that the prolonged use of the X-ray sometimes produces cancer. Admitting this how in the world is it possible for any living germ to live or thrive under repeated exposures to the X-ray which we know to be so fatal to them.

Another strong argument against a parasitic origin of cancer is what Dr. Gustav Enterer, of Chicago, has to say:

"While I do not intend to discourage research in that direction, I wish to state that I have never been able to believe that parasites are or may be the cause of carcinoma. Probably the strongest reason against a parasitic cause lies in the fact that in carcinomatous metastasis the cells of the organ do not become infected, and do not participate in the building up of the metastasis which develops from the invading cells. I have first advanced this reason at a meeting of the Chicago Pathological Society, Dec. 14, 1895, and I still consider this fact of the highest importance; it is hard to conceive that such would be the case if the invading cells included parasites."

GEOGRAPHICAL DISTRIBUTION.

Cancer is very prevalent in our own country, that is in the United States. San Francisco takes the lead, next Buffalo, then New York City. On examining a cancer map of the United States we find the darkest area extending along the coast of California and

Oregon, with a lightening up of color until we reach the North East and Middle States which are very dark. All the territory lying south of the same latitude as that of Virginia, Tennessee, and Arkansas the coloring is very light, which is due to the great negro population in these states. The negro we know is rarely affected with cancer. The combined mortality of the seven largest American cities has over doubled in twenty-eight (28) years. During 1898 it caused over 50,000 deaths and it is reasonable to suppose that within the last year there has been a mortality of at least one hundred thousand. This is mere guess work on my part, as I have been unable to obtain the latest census reports of the United States, being largely guided by the census of 1900. In England and Wales deaths from cancer have more than doubled within the last twenty (20) years. No other diseases can show such an immense increase. It is unknown in the polar regions, Algiers, Chili and Borneo, and very rare in China and New Guinea, while in Japan there are 25,000 deaths each year. Cancer of the uterus is almost unknown among the full blooded African negroes. So we see that race, climate and environment has something to do with cancer.

Dr. Senn in the *American Journal*, 1906, said: "During my trip last summer to the very heart of the Arctic, to within 260 miles of the North Pole, I made special observation and inquiry in reference to the occurrence of tumors among the Aborigines. These people have lived for unknown centuries on an exclusive animal diet, blubber, and meat; they do not know the taste of a single vegetable diet; they are the filthiest people in the world as they never wash themselves and wear furs throughout the year and yet they appear to be immune to tumor formation of any kind." The idea occurred to him that this immunity might be due to the iodine contained in the food obtained from sea animals. We know that the North American Indian lived principally on an animal diet and it is said he is still exempt from this disease.

From all this information concerning the different races, cancer must be a disease of civilization.

Even the well-fed closely housed poodle dog is frequently attacked with sarcoma. It is impossible to explain why wild animals and birds have cancer, when we realize that so long as man lived in a primitive state he was exempt from malignant tumors. Another very peculiar thing, that the death rate is higher in the rural districts and smaller towns than in the cities. That those employed in hard out-door work have a higher cancer mortality than the sedentary classes.

PREDISPOSING CAUSES.

We all know that advanced age plays an important role in the etiology of cancer, out of 9,906 cases reported there were only nineteen (19) less than twenty (20) years of age. I have seen two cases of sarcoma of the eyeball in infants under three (3) years of age, no doubt of a prenatal origin, as heredity seems to be a predisposing cause. It has been observed in mice whose progeny had been subjected to direct inoculations. I saw an aged woman die of a mole on the right side of the temple which became malignant and a few years later witnessed the same condition in her oldest daughter, which strange to say originated from a mole in the identical locality as that of her mother. Was this a mere coincidence or was it hereditary? I am inclined to believe the latter.

Trauma or prolonged irritation is a predisposing cause, for instance of the lip and tongue from a jagged tooth, lacerations of the cervix in child bearing women, gallstones, ulcers of the stomach, scar tissue, benign tumors, moles and senile warts may become malignant from constant irritation. Justly or unjustly smoking has been accused of producing epithelioma of the lower lip, tongue and tonsil, especially by the use of the pipe. It is singular, however, that in many countries where cigarette smoking is practiced to the greatest excess like Turkey, Palestine, Algiers and Morocco, epithelioma of the lip and mouth is of rare occurrence, this goes to prove that actinic rays or tobacco has but little to do with cancer. The habit of "betel chewing" so generally practiced throughout India, is unquestionably responsible for the great prevalence of epithelioma of the mouth in that country. We no longer hear of Chimney Sweep's cancer as this occupation has been abandoned owing to better facilities for cleaning chimneys. On the other hand we hear of Sailor's Cancer supposed to be due to prolonged exposure to sun rays. In beer drinkers and those using all kinds of alcoholic beverages the death rate is lower than that found in the more moderate consumers of alcohol, which may be explained, that many of the excessive users of alcohol never live to reach the cancerous age. Ministers are prone to cancer because they have a higher life average than some other occupations.

On comparing the different occupations in regard to the frequency of cancer we are surprised to find the great mortality occurring in those who do hard out-door work; leading the list with a death rate of 126.6. Then follows sailors and fishermen, 113.1. Then nurses and midwives 105 per cent; Blacksmiths 107.3; clergymen 102.2; masons 98 and farm laborers 87 per cent.

An argument against the theory that alco-

hol is a predisposing cause of cancer is that the average in those of the public entertainment class is only 35.3, being the lowest of all the group. The average under this heading for saloon and restaurant keepers is only 28 per cent. It can also be shown that the consumption of beer has no direct influence on cancer, by comparing the rates in certain cities that are largely inhabited by Germans and are the centers of breweries. For instance Milwaukee, Cincinnati and St. Louis the death rate is much lower than in a great many other cities where the environment is different. This list also shows that 63.1 per cent of all cancer are in women and 36.9 per cent in men. This can be explained when we take into consideration the frequent occurrence of cancer of the uterus and breast. Cancer of the stomach is a little higher in man than in woman, while cancer of the throat, mouth and tongue is three and a half times more frequent in men. Over 50 per cent of cancers in men occur in the stomach. Carcinoma of the stomach is a very rare disease in youth. Regel in Nothnagel's Practice reports a case in an infant of five weeks. Also another case in a boy one and one-half years old, both cases no doubt being congenital. Kelly saw a case of carcinoma of the uterus in a girl twelve years of age.

Cancer begins primarily in the epithelial cells. Dr. J. S. Pilcher describes the condition as follows:

"It is in the lawless proliferation of pre-existing epithelial cells in luxuriant, irregularly arranged masses that invades underlying and surrounding tissues, premeating them, and finally themselves attaining a mass which can no longer be adequately nourished by an accessible blood supply and which itself then falls into central decay, while at the periphery the process still goes on that cancer consists."

To attempt to give the diagnosis, pathology and symptomatology of the various forms of cancer would lengthen this paper far beyond the limit, so I shall close with a few remarks on treatment.

There are two very important things that we general practitioners should never forget:

First. That all cancers in any part of the body are at first local and that this is the only time when proper treatment will perfect a permanent cure.

Second. We should be able to make an early diagnosis. Dr. Rufus B. Hall, of Cincinnati, said to me two years ago, in referring to the diagnosis of malignant disease, "that quite a number of physicians' wives and daughters whom he had operated on for cancer of the uterus and breast, had never been diagnosed as such by their fathers or has-

bands." This being true, we can easily imagine that a far greater number were overlooked or undiagnosed outside of their immediate families. That such a condition should exist among our profession is hardly pardonable. If we are unable to make a correct diagnosis of these cases ourselves, it is certainly our duty to refer them to skilled men who are competent to do so. Thirty thousand women die of cancer of the uterus in the United States every year. Admitting that women often neglect to consult a physician when afflicted with this disease we are nevertheless, greatly responsible for this enormous mortality.

The advice of our old-time physicians and I am sorry to say, a few of our modern ones "to let it alone; if it does not bother you, don't bother it" etc., has deprived many a patient of his life, who would have been saved by a thorough removal of the disease tissue. Most of the laity look upon cancer as an incurable disease and we should do all in our power to eradicate such a belief. Tell them that the skillful surgeon by early operations are curing from 30 to 50 per cent. of cases of cancer of the uterus, and eighty (80) per cent. of cancer of the breast remain well, if done within six (6) months of the development; that they are curing a number of cases of cancer of the stomach and intestinal tract, as well as those of the kidney and bladder. Tell them that over ninety (90) per cent. of superficial or skin cancers can be absolutely cured by cauterizing, caustic or X-ray. "Crile estimates that 80,000 unsuspecting people in this country at this moment will be affected with incurable cancer within six months." Just think what an early diagnosis and treatment means to these eighty thousand, a saving of at least 20,000 lives. We must enlighten the public on this subject as we are so earnestly and so successfully doing with that of tuberculosis. Inform the women that the slightest hemorrhage coming on several years after the menopause does not, as a rule, mean the re-establishment of menstruation, but in the great majority of cases means uterine cancer, and that the vast majority of abrasions and tumors of the breast are of a malignant origin. A pus and blood discharge from the rectum does not in all cases indicate hemorrhoids but may be due to malignancy. Eighty per cent. of all cases of the intestinal tract occur in the rectum, this being true, think of how many lives could be saved by an early examination with the proctoscope. In cancer of the bladder we can make a positive diagnosis by the aid of the cystoscope and microscope, and that of the stomach by the absence of free hydrochloric acid in the test meal, however this is not infallible.

It is claimed that in no part of the body

are cancerous tumors less disposed to return after their removal than in the rectum, except epithelial growths of the lip. Incision is the best treatment for internal cancers, also for cancer of the breast; the Halstead operation being the best in the vast majority of cases, when followed up with X-rays.

Paget's disease of the nipple is nothing more or less than an early stage of cancer of the breast, and it should be removed by the knife, however it is not necessary to do an extensive mutilating operation in these cases.

Amputation in a great majority of cases of sarcoma of the long bones is the only life-saving treatment. Although some cases have been reported as cured by the X-rays.

In epithelioma of the lower lip we should go far beyond the healthy tissue if we expect a permanent cure, and if there is a glandular involvement, they should be removed by an extensive dissection. I can recall four successful operations I have done within the last eleven years in men aged 35, 42, 68 and 70 all living at the present time and in excellent health. In the one aged 70, fully one-half of the lip was removed; in this case the lip was so shortened that it was necessary to remove the lower front teeth. Even in the hopeless cases of cancer, such as the rectum and uterus an operation is justifiable in order to prolong life, and make the patient more comfortable. Superficial caustics like nitrate of silver and carbolic acid are dangerous as they frequently aggravate and do not go deep enough, however, Marsden's paste is very penetrating and will remove sufficient tissue for a cure; in some cases it is best to remove some of the growth with a sharp curet and then apply the paste; this is also an advantage when using X-ray and carbon dioxide snow. Ravolia reports excellent results from the use of a 40 per cent. solution of formaldehyde also from the use of solid permanganate potassium. Recently I have been getting good results by the use of carbon dioxide snow, which destroys tissue by rapid freezing, usually requiring only from ten to thirty seconds. This snow is so cold that it has been estimated to be as low as 160 degrees below zero. Dr. Pusey, of Chicago, discovered this treatment in 1907. In some respects it has the advantage over X-rays as it usually requires only one treatment and healing takes place within two weeks.

The X-ray is the best for epithelioma of the lip, nose and eyelids as it does not leave disfiguring scars that we so often see after the use of the knife or caustics. Just why the X-ray fails to cure deep-seated cancers, we do not know, probably due to the obstruction of the rays by the skin and underlying tissues. Under an improved technic we may before

long get better results. Its possibilities are beyond the conception of man.

Radium is far superior to some of the remedies mentioned as when the disease is located in a cavity such as the mouth, throat, rectum and vagina. Recently a radium hospital has been established in London, where experiments are now going on, and it is reasonable to believe that ere long marvelous cures will be reported. Out of the combined workers in the field of investigators in cancer research, a cure is bound to come. It may come through serum treatment, it may come through the light treatment or through chemotherapy. Who knows? A crown of fame awaits the discoverer.

CHYLURIA.*

By FAYETTE DUNLAP, Danville.

January 19th, 1912, a young man age 18, came to my office. He was in robust health and a laborer. He consulted me regarding frequent urination with the additional information that the entire collection of urine seemed to go to foam.

He passed four ounces of urine in a beaker and the two facts most noticeable were a slight opalescence and the great amount of foam. Saccharine urine oftentimes bubbles and foams on agitation, and suspecting that, I resorted to the hydrometer and found a specific gravity of 1.004. This low range indicated nephritis rather than glycosuria. The sugar test was nil and the heat and acid test revealed a large coagulum. I then resorted to the centrifuge with the unlooked for disclosure that there was precipitated a firm whitish-pinkish mass with a very clear urine above. The microscope revealed a mass of very fine fat globules, red corpuscles and a few leucocytes. Upon brisk agitation the entire volume of urine became foam and while in this state I added sulphuric ether and it immediately resolved itself into the clear state again, thus practically confirming the suspected condition of chyle in the urine.

The entrance of the contents of the lymph channels into some part of the urinary tract usually directly into the bladder can be caused by traumatism, erosion, by means of a fistulous tract, and in the tropics by the presence in the blood of the parasite *filaria sanguinis hominis*. In my patient the prominent symptom was frequent and abundant urine and in the beginning of the attack painful symptoms strikingly like the passage of a calculus through the ureter. I noted that when the urine was allowed to stand undisturbed in the tube that a firm tough jelly clot would form, and my interpretation of the

pain was the passage of a mass of this kind from the pelvis down the ureter. I searched diligently through several specimens for the ova of the *filaria* but found none and two occasions a freshly drawn blood drop for the parasite itself but found nothing. There were no evidence of kidney casts for the experience has been that these cases oftentimes result in chronic nephritis. The patient's general condition is excellent, strength only slightly impaired, as I am of the opinion that this patient has an accidental chyluria there is no treatment promising anything, hence nothing was prescribed save an emulsion of cod liver oil to replace in part the perpetual loss of the lymph.

REMARKS ON DIAGNOSIS OF POLIOMYELITIS WITH MISLEADING SYMPTOMS.

By TOM A. WILLIAMS, Washington D. C.

In 1910 there were in Washington, D. C., 500 cases of poliomyelitis within three months. A study was made of the early pathology of the condition in the cerebro-spinal fluid in 11 cases; and leucocytosis was found in the earlier stages, followed within a few days, by the appearance of large macrophages and then a lymphocytosis. In some of these cells were found bodies resembling those of Leishman Donovan.

No early symptoms were discovered which would enable one to affirm that a case was one of poliomyelitis before loss of reflexes or paralysis ensued. It seems that in times when the disease is expected, all febrile cases should be isolated for some days, at least. That might be a wise measure in febrile disease always.

One gratifying feature of the epidemiology is that this year just gone, this summer, there have been very few cases. It would seem, therefore, that an epidemic sweeps all the susceptible individuals into its net, and leaves the community largely immunized.

The unusual types of the disease have not been very abundant in the report; although to me they have appeared very abundant; for it was these more difficult cases that I mainly saw.

It was the bulbar cases that are the most likely to escape diagnosis. One such patient I saw after the disease had subsided, leaving only a complete paralysis of the serratus magnus muscle and a slight weakness of the deloid of the same side, had had an acute bulbar attack in which she nearly choked to death, in which there was a strabismus of one

*Read before the Boyle County Medical Society.

eye, facial paresis, and in which swallowing was impossible.

There are no pathological evidences that the peripheral nerves are affected by this disease. The clinical similarity in some cases is due to the irritation of the spinal roots in the meninges, which renders the afferent nervous system more sensitive. This, along with the general febrile condition, is the cause of the tenderness found in these cases, in which simple pressure excites pain similar to that so characteristic of peripheral neuritis. But the diagnosis in most cases is simply made, by studying the distribution of the paralysis, which in polyneuritis is uniform and general, although it may vary somewhat in degree, but never to the extent of completely paralyzing some muscle groups and entirely sparing others, which is, as we know, the rule in poliomyelitis. Some cases of acute ascending paralysis which die cannot, however, be diagnosed with certainty, unless the history is clear or the sensory symptoms are pronounced or a post-mortem is made.

Cases with symptoms of spastic paralysis are quite puzzling if the lower motor neuron affection is indistinct. In one remarkable case I saw this spring, there was incomplete transverse myelitis, with only partial sensory symptoms at inception, great pain in the testicles, followed by slight paralysis of the quadratus femoris on the one side, and a weakness of knee reflex and ankle clonus on both sides. In this case, which I diagnosed as probably poliomyelitis, the cerebro-spinal fluid was free from excess of cells; but we inoculated this into a monkey; and this monkey became paralyzed about six months afterwards.

The patient was out of bed within ten days, and has apparently completely recovered.

CAESAREAN SECTION—FIRST IN AMERICA.*

By E. S. McKee, Cincinnati.

Dr. John L. Richmond, at Newton, Ohio, a few miles from Cincinnati, on April 22nd, 1827, made the first recorded Caesarean section in this country. The matter has been most elaborately worked up from all points by Dr. Otto Juettnner, of Cincinnati, in an elaborate address recently delivered at Newton, and published in the Cincinnati *Lancet-Clinic* January 27, 1912. Reprints of Dr. Juettnner, Berkshire, Cincinnati.

Dr. Richmond's patient was a primipara who lived in a log hut hastily thrown together for immediate occupation and unchinked. At the time of operation it was surrounded by

a raging flood for both the Ohio and the Little Miami were raging floods. The hour was midnight and his sole assistant was a lone woman whose entire attention was taken up with holding the only candle and protecting it with a blanket to keep the wind from blowing it out. The operation was favorable to the mother but the child died. He reported his case in the *Drakes Western Journal of the Medical and Physical Sciences*, Vol. III, 1830, p. 435 and is quoted by Juettnner in his address in its entirety. Dr. Richmond graduated from the Medical College of Ohio in its first class, 1822. He practiced and preached in Newton, for he was also a Baptist minister, he performed signal service in the cholera epidemic of 1831, contracting the disease himself. After recovery, being in shattered health he removed to Indiana where he lived in Pendleton, Indianapolis and Covington at which latter city he died in 1855 and lies buried in Springdale cemetery, Lafayette, Indiana. Much of the information was obtained from his granddaughter who is now living in London, the wife of the American Counsel. April 22nd, 1912 there will be a gathering of medical men in Newton to erect a tablet to the memory of Richmond where he performed his great work.

RELATION OF RENAL ACTIVITY TO SURGICAL OPERATION.*

By E. O. Smith, Cincinnati.

The success or failure of a major operation depends largely upon the activity of the kidneys, of course barring faulty technic and bad surgical judgment of operator.

The functional activity of the kidney may be influenced by the shock incident to a major operation, by the anesthetic, by trauma to one or the other kidney, by calculi, or by ureteral obstruction from any cause. Hysterical anuria or oliguria, if such a thing is possible, seldom follows operations.

There are still some of us who are skeptical as to a reflex anuria. A sudden blocking of one ureter effects the kidney on the opposite side by suddenly throwing upon it increased work, and if the kidney is normal it will quickly adjust itself. Anuria following ureteral catheterization is due to the fact that the patients have been deprived of water prior to examination. To avoid this, give plenty of water just before the examination. The effect of traumatic disturbance of one kidney in producing anuria is due to the shock and to the call for double duty by the other kidney. All surgeons are familiar with the diminished urine output for several hours after an operation. By many it is considered a mere inci-

*Read before the Fayette County Medical Society.

*Read before the Bourbon County Medical Society.

dent unless it is so marked and persists so long that the patient's life is despaired of. The degree of disturbance produced by the above mentioned agencies depends upon the conditions of the kidneys at the time.

If the kidneys are histologically and physiologically normal at the time of the operation I believe that the effect of the anesthetic, shock, etc., on the kidneys will be so slight and so transitory that the patient will suffer no marked or permanent ill effect.

Fisher's theory of nephritis, which has been proved both experimentally and in clinical application, is that the activity of the kidney is altered by the presence of an increased acidosis. He claims that the kidney parenchyma, that is between the blood on one side and the urine on the other, is a colloid material which in the presence of abnormal acidosis becomes edematous and does not permit the passage of water from the blood stream to the uriniferous tubules. In other words this colloid substance takes on water but does not give it up. When the acidosis has been overcome or reduced sufficiently the kidney parenchyma loses its edema and again resumes its function.

Heart and lung lesions, muscular exercise, mental disturbances, disturbances of the renal blood supply, and toxic matters in the blood, all produce an increased acidosis and the symptoms of nephritis. While this applies to nephritis generally it is all the more applicable to post-operative suppression of urine.

It is not all of surgery to make a diagnosis of a surgical lesion and proceed to operate. There are three distinct periods of every surgical case that require special care and attention. The preoperative period, the operation, and the post-operative period.

THE PREOPERATIVE PERIOD.

The preoperative period is the time prior to the operation when the patient should be studied most carefully and prepared for the operation. This period may be a few days, a few weeks, or it may be the only period, if the patient cannot be sufficiently improved to make the operation comparatively safe. During this time the patient is examined most thoroughly as to his heart, lungs, etc., with particular attention to the renal activity.

It has been noticed that when continuous bladder drainage has been instituted, the specific gravity of the urine in some cases was reduced from 1025 to 1008 or 1010. When this occurs or when the specific gravity was low prior to the drainage, operation should not be attempted until this has gone up to 1020 or more. There is one exception to this and that is when there is a decided polyuria in which case there is a good output of urea, etc. On the other hand we may have a pa-

tient with a high specific gravity and high percentage of urea but still be a bad surgical risk, because of diminished amount of urine. A careful urinalysis should precede every operation.

It is best to make a further study of the functional activity of the kidneys before operation. This is based upon the observations that normal kidneys remove from the circulation certain drugs that have been introduced, within a certain time and that marked deviations from this time represents abnormal kidneys. Numerous tests have been suggested, but only three are now looked upon as being reliable. They are phloridzin, indigo-carmin, and phenol-sulphone-phthalein.

Phloridzin has the peculiar property of producing a glycosuria in normal kidneys. In kidney disease the glycosuria either does not appear at all or is delayed. Five milligrams of the drug is introduced subcutaneously and in normal cases sugar appears in the urine in from twenty to thirty minutes. The urine is collected and examined for two or three hours having reached its maximum at the end of the first hour.

Indigo-carmin is best introduced into the gluteal region, using 4 c.c. of a 0.4 per cent. solution. If the kidneys are normal the urine will show a bluish tinge in fifteen to eighteen minutes, after the injection. If the appearance is delayed and the color more greenish than blue it indicates diminished kidney activity.

The most reliable and valuable of all is the phenol-sulphone-phthalein test as developed by Rowntree and Gerahly. In brief this consists in introducing into the upper arm 1 cc containing .006 of the drug. This should show in the urine in from fifteen to twenty minutes. During the first hour 40 to 50 per cent of the drug is excreted as is determined by a colorimeter, and 20 to 25 per cent. during the second hour. Variations from these figures indicate damaged kidneys. It can be administered intravenously in which case it appears in the urine in from two to five minutes and a greater percentage (75 to 80) is excreted during the first hour.

This test has proved to be very reliable and has saved surgery a mortality on many occasions. Some cases that showed at first a diminished functional activity at which time they would have been bad surgical risks, after having been treated, improved so much that operations were safely performed.

Others showed no improvement from treatment and died the "natural way" within a few weeks. If the renal function is normal and there are no other contraindications for operation a very short period of preparation is all that is necessary. It is my opinion that a patient is better prepared to withstand an

operation. If muscular activity produces acidosis, rest will diminish it. Of course there are emergency cases that must be deprived of the benefit of the preparation treatment.

During the preparatory period the patient should be well fed with easily digested, nutritious food containing few proteids. He should have plenty of water and above all things his system should not be depleted of water by copious purging with salines immediately before the operation. The intestinal tract should be thoroughly, but gently, emptied by the administration of castor oil the day before and an enema a few hours before the operation. He is allowed to drink water up to within one hour of the operation. The kidneys cannot secrete urine when the system has been deprived of its water. In surgery of the urinary tract, particularly prostatic surgery, a great deal can be done to help the patient by continuous bladder drainage through a catheter retained in the ureter for a few days prior to operation, or in very bad cases suprapubic cystostomy performed under local anesthesia. In this way back pressure is removed from the kidneys and they will functionate much better, thus improving the patient's condition and increasing his resistance to shock, sepsis, and post-operative anuria.

Having decided to operate, the patient should be prepared and anesthetized with as little confusion as is possible. This is an anxious time for most patients, and their mental state should be as composed as possible. If the patient is particularly nervous he should not be required to walk into the operating room, mount the table, and there take the anesthetic. This should be administered in a near-by room where all is quiet. Ether is the anesthetic to be generally preferred, but in bad risks, such as old people and those known to have a bad heart or bad kidneys, where operation is imperative, nitrous oxide-oxygen is the anesthetic of choice. There is less toxicity carried into the circulation from this than from any other anesthetic and less cardiac and respiratory depression, hence less liability to kidney disturbance. The patient is not left saturated with the anesthetic and is seldom troubled with nausea and vomiting afterwards.

The operation should be done as rapidly as is consistent with good work; for the longer the operation the greater the shock, and the greater the shock the greater the circulatory disturbance, in consequence of which the blood supply to the kidney is diminished, a very apparent cause of renal inactivity. The surgeon should not waste any time lecturing or demonstrating the operation to bystanders, the same as if he had a cadaver before him.

His whole duty is to the patient who is under an anesthetic and besides, surgeons are not made by watching surgery at a distance for ten days or two weeks. In short everything should be done to lessen the shock and amount of anesthetic.

The surgeon's duties to the patient do not end with the introduction of the last suture. A great deal can be done in the next few hours to sustain renal activity and to prevent urinary suppression, immediately following the anesthetic the patient should be given oxygen inhalations. In old people and bad risks this should be continued for several hours. This same class of cases should receive at least two pints of saline solution under the skin and when returned to their beds proctoclysis of saline solution about forty drops to the minute should be started and continued for several hours. Repeated at intervals for several days if there are any evidences of renal failure. As soon as the patient awakens from the anesthetic he is given hot water and plenty of it. The conditions existing during an operation are those that tend to produce an inactivity of the kidneys and these can best be overcome by increasing the blood pressure, by increasing amount of fluid in the vessels which bring more blood to the kidneys. The toxicity and acidity of the blood has been reduced by dilution and salt.

The former custom of withholding all fluids from the patient for twenty-four hours after operation and until drastic catharsis has been established, was all wrong and has no doubt worked greater disaster than we know.

Hiccough and persistent vomiting following operations is indicative of diminished renal activity and should be looked upon as a symptom or a note of warning rather than an independent complication, calling for special treatment.

Thus far we have considered those phases of the patient and the operation that would be prophylactic in nature. When these plans are followed there will be few cases of post-operative anuria. If shock and anesthetic are reduced to a minimum and proper care of patient before, during, and after operation, anuria will develop only in the desperate cases. When anuria does occur the best treatment is fluid introduced directly into the circulation, sweating, and morphine. Immediately on the development of suppression sufficient morphine should be given to keep the patient quiet. Formerly only salt solution was given intravenously, but Fischer's alkaline solution has proven more efficacious in acute anuria. This consists of giving intravenously in desperate cases, or by proctoclysis, forty to fifty drops per minute, in less pronounced cases a solution made as follows: sodium carbonate crystals 10 grams dissolved

in 200 c.c. distilled water and allowed to cool. This is then added to salt solution 14 grams to 1000 c.c. distilled water, sterilized and cooled. If these solutions are continued while hot sodium hydroxide will be formed which is very irritating. If given intravenously this amount can be slowly introduced and repeated in a few hours without harm. Very gratifying results have followed the use of this solution per rectum. In whatever manner it is introduced into the circulation, renal activity is resumed in a few hours. One must not give up if the effect seems transitory but it should be given often enough to keep up the effect until urine secretion has been produced and sustained.

As the skin is an avenue of elimination, sweating should be encouraged.

CASE OF CYST OF THE MESENTERY.

By A. H. BARKLEY, Lexington.

Cysts of the mesentery are by no means common. In some of the largest clinics they are seldom met with. They vary in size and in the majority of instances they excite no suspicion of their presence unless they are so located that they exert pressure or produce obstructive symptoms and even then they may escape detection unless of sufficient size to be palpated.

They are more frequent than solid tumors and their etiology and pathology are still not well developed.

The report of the following may be of interest.

On November 2, 1911, the writer saw this patient in her home, she had been in bed for ten days previous complaining of an intense soreness in the left side. Examination revealed the following: Mrs. H., age 32, white, married ten years, never pregnant, family history negative also personal history except when 18 years of age was struck in the left side by a horse, pain at intervals for a number of years that was more or less intense. When seen on November 2, 1911, there was a distinct tumor in the left hypochondriac region which was distinctly fluctuating and slightly movable. The spleen could be made out but there was a question regarding the left kidney as a diagnosis of hydronephrosis had been made with propriety sometime before I saw her as the urine would vary in quantity and there seemed to be some diminution in the size of the tumor.

On November 4, 1911, an incision was made through the left rectus and abdomen opened the tumor presented with the descending colon overlying it, the peritoneum was split and a cyst about the size of a grape-fruit was removed without difficulty. The location was to the outer side of the descending colon just

below the splenic flexure, its removal in no way affected the blood supply of the bowel. The recovery was uneventful.

The contents macroscopically resembled turbid serum.

DEFORMITIES OF CHILDREN.*

By W. A. MCKENNEY, Falmouth.

I have chosen for my subject for discussion deformities occurring after birth, or acquired deformities, deformities existing at birth, while of great importance, are not nearly so much so as those occurring after birth. A great many of them are remedial, they are wholly unpreventable, while in those occurring after birth are better prevented, than cured. Therefore I have selected those occurring after birth as being of the most importance, both to the medical profession and to the public in general.

In writing a paper on this subject I shall endeavor to bring out some points of practical value, rather than to confine myself to any one deformity or any class. Books might be, and are written on the various conditions that are met. I do not expect to advance anything new, but to call your attention to the early recognition, as it is in the borderline cases that are of the most importance, not only to the doctor but the patient as well, for if the doctor is on the lookout for the earliest symptoms he will be able to prevent the majority of deformities that occur. After they do occur they are easily recognized and treatment does not offer so much.

I have divided my subject into three heads 1st, Those resulting from nutritional disturbances or disease; 2nd, mechanical causes; 3rd, habit.

There is one condition that stands out pre-eminent as a cause of deformity, because it occurs at an age of early development, and I shall speak of it more at length than any other, and that is rachitis, it being the most common disease followed by deformity. There are various theories regarding Rickets some claim it is a dystrophy, some believe it is due to toxins received by special inheritance others believe it is due to alimentation. All regard it as constitutional. It occurs between the 6th and 30th month. Bad diet, bad hygienic surroundings, improper food, ignorance, disregard of the laws of nature, as well as inheritance, feeble digestion, defective assimilation, offspring of tubercular or syphilitic parents, are predisposing causes. The symptoms of which are digestive disturbances, restlessness, profuse sweating about the head and face, a loss of flesh or flabby appearance and a failure of development, and

*Read before the Pendleton County Medical Society

terior fontanel fails to close by the usual time the child is slow about cutting teeth, and if the disease has a good hold you will find the ends of the long bones beginning to enlarge, for with this disease is associated the softening of the bones due to the absence of the earthy salts, and by their being soft we can readily see why they will bend in almost any shape. After the disease has become well marked you may find almost any deformity of the bones. I shall only mention a few without any attempt to describe them. First in importance is deformity of the pelvis, due to a narrowing of all diameters, and of great importance to the obstetrician; shortening of the stature due to bending of the long bones, such as bow legs; enlargement of the head, caused by failure to close of the sutures and fontanels.

The double jointed appearance caused by the epiphyseal cartilage failing to unite, and the "Rosary" familiar to all. Tuberculosis of bone is of almost as much importance as rickets, especially where it involves the joints, as hip-joint disease, ankylosis of other joints, and atrophy from long continued disease.

2nd. Those conditions due to mechanical obstruction and their results. Enlarged tonsils and adenoids, by obstructing the upper air passages, interfere with the free-passage of air through the proper channel, the nose, and in order to gain relief the child breathes through the mouth. In time this becomes a fixed habit which after a time brings about certain changes of form and features. By the continual pull of the muscles on the superior maxilla, the masseters and buccinators pulling downward they gradually narrow the bones from side to side, while at the same time the face becomes longer and narrower, changed in all directions toward the point of least resistance. By the action of the levator and tensor palati muscles to increase the breathing space, they pull the palate upward and backward.

And from these various actions of the muscles the arch of the palate is greatly increased. The whole combined action lengthens the face and also narrows it, the nose does not develop from disuse, and the whole physiognomy is changed. Because of the obstructed breathing when there is need for more forcible respiratory action, the shoulders and base of scapular are fixed and the combined force of the trapezius, the pectoralis minor, serratus superior and inferior and the rhomboidei acting on these parts, gradually pull the shoulder tips forward and the scapular outward, giving it the peculiar winged appearance, and the constant pull on the shoulder gives the round shoulder or humped back appearance, which is a deformity, for no one ever saw a humped back baby born. One of

the worst features of this bending forward is to compress the lungs thus narrowing the breathing space and predisposing to tuberculosis.

HABIT DEFORMITIES.

Those occurring from improper positions of the body when long continued. This perhaps does not properly belong under the head of deformities of children but it is so closely allied to those just mentioned, I feel that it will not go amiss to bring them up here, because they occur at an age of early development. The various curvatures of the spine, due to carrying weights as a baby astride the hip, wearing high-heeled shoes, and improper fitting shoes, throws the weight of the body on the ball of the foot, and the heel, without any support to the arch, this causes it to give way thus causing flat foot. Also young girls about the age of puberty, from wearing high-heeled shoes it causes the peculiar kangaroo walk, from the bending forward of the knees, in order to keep the proper equilibrium of the body, this throws it out of its natural shape and may cause a greater curvature of the spine in the lumbar region by throwing back the shoulders. And the rotating outward and backward of the greater trochanters, broaden the hips and consequently narrowing the pelvis from before backward. A condition that is of great importance to the obstetrician. I only mention a few examples as any unnatural position of the body long continued in the young, growing child will bring about abnormalities.

Now a few words as to the treatment. In all the conditions that I have mentioned the ounce of prevention is worth more than the pound of cure. Orthopedists have invented various ingenious devices for the correction of deformities, and surgery has been employed to a large extent, and some of the most beautiful technique worked out, and the results have been remarkable. Other means such as gymnastics and massage, all have been employed to correct the evils, but the prevention is worth them all.

I have endeavored in a general way to speak of some of the common deformities, their causes, and their results, and I hope these few homely remarks will cause you all to be more on the lookout for them, and that you will not pass them up lightly, but will endeavor to instruct those that are responsible for the child, of the results of neglecting a condition that may be easily prevented at first, but if permitted to go on without any care will remain as a permanent injury throughout the life of the individual if it does not greatly shorten their days.

ATYPICAL CASE OF PERITONITIS WITH OBSCURE ORIGIN.*

By W. S. GABLIART, Mackville.

Mrs. J., age 35, mother of three children. Had been healthy all her life. After doing a hard morning's work, ate a hearty dinner of sausage and other things. In the evening she complained of headache, pains in back and limbs, which was relieved by acetanilid and codeine.

The following day she seemed still better. The next day, being the third day, I was called to see her for the first time. She had taken a dose of salts the night before and had had forty bowel actions that day. The actions were watery and only a very small quantity of blood, temperature 102 1-2, pulse 120. Slight distention of abdomen, and tenderness all over abdomen on deep pressure, but no localized pain. Had vomited once. Vaginal examination negative. Urine normal.

Following day (fourth) temperature 102, pulse 120. Distention slightly increased.

Next day (fifth) all symptoms had grown worse, and had developed some pain over abdomen, first here and then there, but never localized.

Sixth day, temperature 101, pulse 120, and seemed much brighter.

Seventh day distention was great, and the pinched features of a general peritonitis had developed. She died on the eighth day.

The treatment consisted in the relief of the headache and muscular pains by acetanilid and codeine, followed by magnesium sulphate at bedtime.

The severe diarrhea could only be controlled by morphine, 1-4 gr. hypodermically, checking from 40 actions down to 7 the following day, and two the third day.

Turpentine stupes were used over abdomen medicated enemas were given, Fowler-Murphy method of treatment was carried out without any results. Stimulants were given, and only late in the disease was it necessary to use any remedy for the relief of pain.

Dr. M. W. Hyatt saw her with me and we considered it a very interesting case in regards to cause, irregular course and absence of many of the prominent symptoms of peritonitis.

CASE REPORT OF QUADRUPLETS.

By C. T. RICKETTS, Bright Shade.

Mrs. Goodman Lawson, on August 25, 1911, gave birth to four children, three girls and one boy.

The mother is twenty-one years of age, has one other child. This being her second time in pregnancy. Two of the children were born dead, and the other two lived over an hour. The mother claims twenty days before her time, but the children looked to me to be at her time for delivery. The largest child, six pounds, which was dead, first born. The second born was living, five pounds. The third born was living, three and one-half pounds. The fourth, born dead, four pounds. The skin of the dead children was rather blue or dark.

Four weeks before her delivery I was called to see her. She complained of being too full and smothery. She felt movement only high up in the right side of the abdomen. She was also having trouble with lower bowel. I made a digital examination and found the mouth of womb much thickened, but no dilatation. She was still active and kept on her feet all the time during the day up to the delivery. She is a woman that will weigh 140 pounds, tall and rather slender, but a stout woman. She has always been used to hard work, such as farm work, goes into the field with her husband. They are very poor people. The father of this mother at one time had syphilis. He has two girls, one older and the other younger than this mother, which show the effects of the disease.

The father of the children is a low, heavy-set fellow and strong.

If anything more is wanted to this case, please let me know and I will furnish it at once with pleasure.

FIBRO-ADENOMA; REPORT OF CASE.*

By C. R. GARR, Flemingsburg.

I saw this case with Drs. Reeves and Evans of Bath county. Patient, female; age 15, white. Family and personal history good. Appearance, healthy and robust. Menstruation fully established at the age of 14 years.

About one year before the right mammary gland began to develop more markedly than the left. So rapid was its growth, that on account of its weight, having to be carried in a sling, and resulting deformity, that the patient readily consented to sacrifice the breast. There was no retraction of the nipple, glandular enlargement, adhesions to the skin, nor cachexia.

On December 6, 1906, assisted by Drs

*Read before the Fleming County Medical Society.

Reeves and Evans and Dr. Brice, of Flemingsburg, the right breast was removed, the mass weighing five pounds. The tumor was firm, elastic, lobulated, and surrounded by a capsule. While no pathological examination was made, the macroscopical appearance did not indicate a malignancy. It was not necessary to ligate any blood-vessels. The case made an uninterrupted recovery and there has been no recurrence of any trouble.

Our text-books do not mention this as any rare condition, but this was the first and only case of the kind that I have encountered during thirty years in a country practice.

HOW DO WE AND HOW SHOULD WE TREAT A BROTHER PHYSICIAN?*

By R. T. HOCKER, Arlington.

The young doctor having finished his office and college course, enters upon his life work expecting every physician to be his friend. It is perfectly natural for him to expect a hearty welcome to the active duties of the profession, and kind, courteous treatment from its members. Having spent more than two years at college, he has found no body of men truer to each other than his fellow students. They often being referred to as clanish. This principal prevailing among them being possibly equalled only by the clans of Scotland of two or three centuries ago, or among veterans of the army.

But the awakening will probably soon come, not requiring but a brief period of time. The old, the middle aged and even the young "M. D.," of three or four years' experience are watching and waiting.

The first great crime preferred against him, is that of being young. The older men will occasionally or at long intervals strain their generosity almost or quite to the limit by "dawning him with their faint praise" by the remark: "He is a promising young man." Sometimes enlarging by suggesting that when he has ten or fifteen years' experience, he will probably be a pretty good doctor, sometimes kindly adding that when his experience in years has equalled mine.

Fortunately in some respects he gets well of his youth; then he too has profited by his experience, and pays doubtful compliments to his fellow physicians.

Doctors, like members of other professions, are not all bad, nor are they of that class, uniformly on bad behavior, fortunately some of them act almost invariably as gentlemen should, who are identified with a profession second in point of responsibility and worthiness to none save that of the clergy.

They, dealing with the morals and souls of

men, while we look after the well being of their bodies upon which depend the mental development to a great degree, and largely the moral deportment is influenced by these.

We sometimes avoid, instead of seeking to win the friendship of our neighbors. We listen to criticisms on his intelligence, his moral character, his ability as a practitioner, and his charges referred to as unreasonable. A shameful practice is entering into an agreement with a doctor in a neighboring town or community to invariably have him called when a consultant is needed. Too often it occurs that the consultant just happens to arrive first and proceeds to enlarge on diagnosis; he thinks and he knows he has no moral right to do either. Sometimes by a word or look he casts a stigma on the regular attendant, that he can never outlive, before his departure the great man announces even in the gravest cases "I can see nothing to keep this patient from getting well," thereby depriving the attending physician of his hard-earned laurels, in the event of recovery and in the case of death the result is much worse.

We should refrain from arming, button-holing and hugging the good patrons of other doctors. We allow a feeling of jealousy to enter our breasts toward another whose only offense is his business exceeds ours. Surely we have no right to complain provided he has won it by honorable means. We often dislike a new comer for no other reason than that he has come.

We act sometimes as though we felt ourselves superior to another, even socially and are careful that they be impressed with our higher scientific attainments. A few other failings are cynicism, crustiness and a disposition to quarrel and ungraciousness.

"Lest we forget." The young doctor refers to the elderly one as an "old fossil, he was possibly years ago a comparatively good physician, but he is out of date now." Be it said to his credit he adds to his generous treatment by saying, "Don't mention this, the old gentleman has always been very kind to me."

From what sounds pessimistic, we turn to the other side and hope to draw a faint picture of what ought to prevail among us, making our lives pleasanter and raising our profession in the estimation of the laity. We ought to greet each other cordially, cultivate fraternal relations, regarding each other as colleagues, co-workers in behalf of the afflicted and not as competitors. Our business naturally isolates us from each other. We ought to identify ourselves with and take an active interest in at least the local medical societies, and better still include the State society and American Medical Association, both for improvement in scientific attainments and becoming better ac-

*Read before the Carlisle County Medical Society.

quainted, the invariable result being that our affection for each other is intensified.

We ought to admit any man to fellowship among us whose deportment as a doctor is just possibly decent; request consultation in all cases of gravity or when there is doubt as to the diagnosis or treatment.

Both parties should be punctual in meeting the appointment, being exactly on time when possible; the attendant rarely causes trouble, the consultant should be perfectly fair, protecting his brother fully; endorsing his treatment or as near it as he can conscientiously, if he can not approve say nothing. Radical changes in treatment are, be it said to our credit, rarely necessary, and ought to be avoided if compatible with the interest of the patient.

Consultation should be strictly private and nothing said should be repeated unless necessary for the protection of the attendant.

We ought to explain that bills will be sent separately. We have no right to object to meeting any one suggested provided he is a man of good attainments and with whom our reputation is safe. The fees of both should be the same, with few exceptions, unless the consultant is a specialist.

It is a great mistake to make concessions. We may with propriety admit that medicine has its limitations but we ought to claim for it everything to which its grand successes entitle it.

In my retiring address as president of the Graves County Medical Society in 1879, I opposed as strong as I could pen it, rendering gratuitous services to ministers. I am proud of my membership in a county medical society that no longer treats these splendid gentlemen as paupers. This practice can not be too strongly condemned. It lowers the status of the profession, and lessens the independence and respectability of the clergy. Charge the established prices for all work unless more than two visits are made in one day, then a reduction we think is admissible. In summing up in all things we should act as becomes gentlemen; if we do not know how, we ought to learn. "Whatsoever ye would that men should do unto you, do ye even so unto them.

The Heart with Myoma.—Neu and Wolff present experimental and anatomic evidence to prove that there is not a special type of injury of the heart due to the presence of a myoma. In six cases in which the hearts were examined, they showed merely the results of injury from excessive losses of blood or wasting away of the body; that is, a tendency to brown atrophy or fatty degeneration or both combined, such as are common in these conditions.

SIMILAR CASES OF EXTREME AGES.

By JAMES Y. WELBORN, Evansville, Ind.

These cases do not present any very important features, yet are reminders of what any of us may see occasionally.

The extreme high age in the one and the young age in the other make them worthy of our attention. The first case, a man 84 years of age, who had been a sturdy man, but a hard drinker until he was 65 years old, at which time he measured his regular drinks sufficient to maintain a sober life. When 72, he noticed a right inguinal hernia, which had given no trouble until the present time. At this examination, I found a strangulated hernia of nine hours duration. The kidneys, heart and blood vessels seemed to be normal. The operation showed a sac filled with the caecum. The appendix, which was caught low in the sac by an adhesion, was held in such a way as to cut off its circulation. The appendix was long, the size of a thumb and perfectly black with gangrene. An appendectomy and herniotomy were then done, the patient making a nice recovery. The patient is now living, four years after the operation.

The second case is a baby five weeks old. The hernia came during the night and with it strangulation. The following morning I opened the sac, finding the caecum with an appendix almost like the first case. This appendix seemed less inflamed but was necrotic and was removed. The circular stitch of silk in the bowel was placed with difficulty owing to the soft tissue. Several stitch holes pulled out. The herniotomy was done by the usual method. This patient also made a perfect recovery. The baby is now a year old and has had no trouble whatever.

THE MODERN TECHNIQUE OF AN OBSTETRICAL CASE INCLUDING THE USE OF FORCEPS.*

By C. B. VAN ARSDALL, Harrodsburg.

The management of an obstetrical case should begin as soon as the fact of conception becomes known. Our duty to our patients demands that we educate them in the matter of putting themselves under the care of a physician at the earliest possible moment of pregnancy. There is probably no class of patients so uniformly neglected as pregnant women. So many of the dangers incident to the pregnant state are avoided altogether, or at least greatly lessened, by intelligent oversight that it cannot be said that our duty to our patients has been discharged until we

*Read before the Central Kentucky Medical Association at Danville, October 19, 1911; also the Mercer County Medical Society, November 14, 1911.

have done everything in our power to make plain this all-important subject. The danger from eclampsia is reduced to a minimum when a skillful and intelligent physician is on the lookout for premonitory symptoms, placenta previa, that terror to the obstetrician, is a much less formidable danger when an intelligent report and investigation of symptoms has been made plain the existence of the condition; extra-uterine pregnancy may be diagnosed in time to save life by a surgical operation; many of the ordinary complications of pregnancy may be escaped or rendered unimportant; abortion and miscarriage avoided and the pregnancy carried to a happy termination; and in general the welfare of the patient and her comfort and peace of mind may be so promoted by a little attention at the right time that we can hardly overestimate the importance of having these patients constantly under our care.

With this preliminary statement of what seems to be of first importance, it will be proper now to consider in detail the actual management of an obstetrical case.

The urine should be frequently examined for albumen. My patients are directed to bring a liberal specimen once a month up to the seventh month, then twice a month. If albumen is present in any considerable quantity, a microscopic examination should be made to determine the presence or absence of casts. It is important that a quantitative test for urea be made in certain cases, but in my experience difficultly is experienced in obtaining the bromine in a usable container. It seems to me, if it could be put up in strong glass pearls similar to those containing amyl nitrite, each containing 1 cc, it would be possible for the general practitioner to make this test with only a tithe of the inconvenience and danger of the present method.

If albumen is present in any considerable amount with a goodly number of casts, the patient should be placed at once on a fluid diet, given diuretics, and watched closely.

The common symptoms of nephritis should be explained to her, with instructions to report as soon as any of them appear. These instructions to the patient, with others that will suggest themselves, may with advantage be embodied in a printed card. The cost is small, and will be more than repaid by the lessened trouble to physician, and added security to patients in the case of any physician who has any considerable obstetrical practice among the more intelligent class of people.

Six weeks before the estimated date of confinement a careful examination should be made for the purpose of determining whether the expected date is approximately correct, as well as to learn if any abnormality exists.

The pelvimeter should be used in every case, as it gives a fairly accurate idea of the size and condition of the pelvis. The measurements should determine the distance between iliac spines, iliac crests, trochanters, and the external conjugate or so-called Baudeloque's diameter. If the measurements bear an approximately normal ratio to each other, an internal examination may be dispensed with; but if these measurements indicate an abnormal pelvis, the diagonal conjugate should be measured per vaginam. At the time of this examination the lying-in room should be inspected and suggestions made as to its preparation and arrangement; at the same time a list of articles to be procured from the druggist and kept in readiness should be furnished the patient. This should include chloroform, ergotole, bichloride tablets or other antiseptics, boric acid, sterile cotton, umbilical tape, sterile vaseline, green soap, alcohol, etc. Directions should be given as to the preparation of sterile sheets, towels, bed and vulval pads, and as to keeping in readiness several bowls or granite-ware basins, fountain syringe etc. The nurse will prepare an abundance of boiled water, both hot and cooled for immediate use.

I direct the patient to call the nurse at once at the onset of pains, and to notify me at once if it is in daytime, so that I may keep in touch with the case during the day; but if the pains begin during the night, to wait until morning, or till the pains become severe enough in the nurse's judgment to require my presence, as I am most likely to be at home in bed and can respond quickly whenever called.

The obstetrician should prepare and keep constantly on hand ready for immediate use a bag containing everything necessary for an ordinary obstetrical case and all the ordinary obstetrical operations. This should include a case of instruments (uterine and perineal), forceps, various antiseptics, ligatures and needles, cathartics, tractor, chloroform and mask, tape for tying the cord, a sterile gown and towels, pelvimeter, vaseline, green soap, powder, and various other small articles, together with a box with top, large enough to contain forceps, during sterilization.

As soon as the pains begin, the patient should take a full bath and a rectal enema. It is not necessary for her to go to bed at first; on the other hand it is probably better for her to be on her feet until the dilatation of the cervix is complete, but after the membranes have ruptured, it is better for her to lie down at once. The legs of the patient should be covered with sterile towels or sheet in such a way as to leave only the vulva exposed. Unnecessary exposure of the patient is always to be avoided. The bed should be a

firm mattress covered with a rubber sheet, over that a plain sheet, then a small rubber sheet under where the patient's hips will lie and over that a draw sheet. The upper sheet and rubber may then be removed after labor, and the first sheet and rubber remain.

In many cases a vaginal examination is not necessary, and in no case should it be made unless it is necessary. There is entirely too much "tinkering" along this line. It subjects the woman to needless pain and annoyance, and adds risk of infection. When it becomes necessary, it should be carried out under the strictest aseptic precautions. The woman's vulva should be washed with soap and water and then with a bichloride solution (1-2000) or other antiseptic solution, and protected by a sterile towel until ready for the examination. If the pubic hair is long, it should be shaved, or at least closely clipped, as it is in the way of all manipulations, and is a frequent source of infection, particularly if forceps are to be used or a laceration repaired. The physician's hands should be scrubbed at least five minutes with water and soap, preferably *sapo viridis*. The nails should then be clipped, cleaned, and filed. This is followed by alcohol and a bichloride solution (1-1000). In going then to the examination the hands should not be allowed to come in contact with bed-clothing or other objects, as all disinfection is thereby rendered futile. The labia are separated by the fingers of the left hand, and the first two fingers of the right hand well anointed with vaseline are carefully inserted without coming in contact with the labia majora, as it is difficult to render these parts absolutely sterile, and the inner surfaces of labia minora and vagina are normally sterile at the time of labor. If repeated examinations become necessary the same rigid technique should be followed at each examination. A simple washing with soap and water is not sufficient preparation for an internal examination. The woman is in great danger from her physician at this point, and many a one has suffered serious consequences, even death in too many instances, as a result of carelessness or laziness or ignorance on the part of the obstetrician. Either of these faults becomes a crime when it endangers the life or health of a human being. It is much better for the physician to rely upon external palpation through the walls of the abdomen, than to resort to vaginal examinations. The four maneuvers ordinarily described will tell him almost as much and almost as accurately, and the danger of infection is eliminated. The position of the child may thus be determined at the preliminary examination and at any time during labor. After a little practice it is surprising how much may be made out in this way.

The nurse should be instructed as to the proper procedures necessary to render her person aseptic, particularly her hands and her clothing. She should wear a fresh, clean gown or dress, should know how to handle the towels, pads, and other dressings, and to care for the patient without contaminating them.

As soon as the pains become expulsive in character, the so-called second stage of labor, an obstetrical tractor may be made use of, thereby dispensing with the necessity of wearing out two or three women pulling on the woman's hands and incidentally saving the patient herself the not inconsiderable soreness resulting therefrom. As the labor nears its close, it is convenient to have a small table near at hand, covered with a clean towel, and carrying the articles ordinarily needed. I place on it chloroform and mask, two hemostats and a small pair of scissors for clamping and cutting the cord, a roll of sterile absorbent cotton, a generous pile of sterile towels, a sterile gown, umbilical tape, and other articles suggested by the individual case.

Chloroform should be given in practically every case; there are very few contra-indications to its use. Women in labor seem to be immune to its dangers. Even severe heart disease is no contra-indication to its use. It should be reserved until the head begins to emerge, and then given at the acme of each pain, and pushed to unconsciousness a minute or two before birth. Much has been written on the subject of protecting the perineum from tears; probably the best that can be done is to hold back the head until the acme of the pain is passed, and then allow it to emerge slowly between pains. After the head is born the fingers should be slipped up around the neck to determine whether the cord is wrapped around it. If it is, it can usually be slipped over the head and freed; if it is wrapped too tightly for this, two artery clamps should be immediately put on and the cord divided between them.

If the child breathes well and seems normal, it may be turned over to the nurse as soon as the cord is ligated; and will require no further attention from the physician except a dressing for the cord. When there is reason to suspect gonorrhoea, each eye should be treated with a drop of silver nitrate solution (one per cent).

The third stage of labor, the extrusion of the placenta, may in many cases be left to nature, without assistance on the part of the physician; if it is not expelled spontaneously within thirty minutes after the birth of the child, it may usually be brought away by the method of Crude, kneading the uterus to force it to contract and using it as a piston to force

down the separated placenta. This should not be done, however, if the rising up of fundus above the level of the naval shows that the placenta has become detached from the uterine wall and lies in the lower uterine segment or in the upper part of the vagina. Kneading may then be dispensed with and the placenta expressed as above; this is Williams's modification of Crede's procedure. It is advisable to examine every placenta carefully to determine whether it has all come away and whether it presents any abnormality.

After the third stage of labor, a dose of ergot may be administered, but this should never be given until after the membranes have all passed. In many cases it is not necessary. I generally give one drachm of the fluid extract, or one-half drachm of Sharp and Dohme's ergotole when the patient is in the country or not easily accessible, with directions to repeat if the lochial discharge is excessive; this will guard against possible serious hemorrhage in my absence. In cases in town or where they can be easily reached I do not give it unless there is excessive bleeding. If the hemorrhage is alarming, it should be given hypodermically deep in the muscles of the gluteal region; for this, ergotole is preferable to the ordinary fluid extract as it is less irritating.

Any lacerations should be looked for and repaired at once, preferably with silk-worm gut sutures. This is too frequently neglected by the general practitioner, either because of laziness, ignorance, carelessness, or a desire to boast that he does not have tears in his lying-in patients; whatever the reason, many thousands of women are doomed thereby to lives of misery and unhappiness. No physician has a right to accept obstetrical patients unless he is prepared and determined to search carefully for and to repair immediately any laceration that may occur. Lacerations will occur, often through no fault of the physician, and he should not look on them as a reflection on his professional ability or skill. Even after the most careful repair, results are sometimes bad owing to the sloughing of the parts; but everything possible should be done to bring about a good result.

After the patient has been cleaned up and made comfortable she should be allowed to rest quietly for several hours. Sterile absorbent cotton or vulvar pads are to be used and the vulva washed with a solution of bichloride of mercury (1:5000) at each change. Her diet should be tea and toast the first day, principally because she will want nothing else. Other articles may gradually be added as her appetite returns, until in a few days she is taking a fairly full diet. It should be very nourishing, so as to promote a free flow of milk. The baby should be put to the

breast soon after birth and three or four times a day until the milk flow is established, and at regular two-hour intervals thereafter. Before and after each nursing the mother's nipples should be gently but thoroughly cleaned with a saturated solution of boric acid, and the baby's mouth similarly treated before nursing; this will prevent many a troublesome case of mammary abscess, as well as of thrush.

When a day or two after delivery the patient shows an elevation of temperature, let us be honest with our patient and with ourselves and call it a case of puerperal infection, mild or severe as the case may be; and not say the woman has "malaria." It is probably true that not one such case in a hundred is malaria, and we should not call it so. Malaria is a rare disease in Central Kentucky, and the term is certainly too loosely employed. As McCrae says, it has the faculty of satisfying the patient, sharing this honor with "rheumatism," "too much uric acid," "something wrong with the liver," but the frequent use of these terms is a sad commentary on the diagnostic ability or honesty of the physician.

In some circumstances it will be found impossible to conform to all the foregoing rules, but they should be carried out as far as possible in every case; and we should be sure that neither carelessness, neglect, nor laziness induces us to omit any possible care that will make for the safety of our patients.

In the use of forceps it must be remembered that there are two important rules to guide us: (1) There must be no marked disproportion between the head of the child and the pelvis of the mother, and (2) Their use must be demanded by the condition of the mother or of the child. Mere saving of time should not induce us to resort to this procedure so dangerous to both mother and child. But when any condition threatens the life of either, and there is no marked disproportion between the child's head and the mother's pelvis, the use of forceps may save one life or perhaps two. The most rigid aseptic technique should be observed in their use, as lacerations are very likely to occur, with the attendant danger of infection.

You are familiar with the terms "low forceps," "mid-forceps," "high forceps," and "forceps on the floating head;" designated according to the position the head occupies, and named in the order of increasing difficulty of application. For the high operation the Tarnier axis-traction forceps are indispensable. The following conditions must be fulfilled before forceps can be safely applied:

1. The presentation must be correct.
2. The cervix must be fully dilated or dilatable.

3. The membranes must be ruptured.

4. As said above, no disproportion must exist between the head and the pelvis.

The application should always be made with the object of applying them to the sides of the head along its occipito-mental diameter, with the parietal bosses in the fenestra of the blades. This results in much less injury to the child, and is much better in other respects, than the so-called pelvic application, which takes into account only the sides of the mother's pelvis, without regard to where the blades catch the baby. This presupposes a careful diagnosis of the position of the head, by the sutures and fontanelles. The first blade applied should be held in the fingers of the right or left hand, according as it is to be applied to the right or left side of the mother's pelvis, and inserted posteriorly on the fingers of the other hand as a guide, very little force being used; then while this blade is held up out of the way by an assistant holding it, a sterile towel is necessary, the other blade is gently introduced on the fingers of the other hand as a guide. Then the blades are locked. The blade that will be most nearly posterior when in position should always be inserted first if possible. Traction is made downward at first, then as the head emerges, upward more and more until at the moment of delivery the handles are up over the abdomen, as the head is born with a movement of extension. The aim should be to imitate natural pains as far as possible, intermittent traction being made so as to distend the outlet gradually. Often the forceps may be removed just before delivery is effected, thus lessening the danger of extensive laceration.

When the occiput is posterior, the forceps are applied according to procedure suggested by Scanzoni. This is merely a double application, the first application being made as if it were an anterior presentation, the head then being rotated to bring the occiput into the anterior quadrant of the pelvis. This throws the curve of the blades downward, so that they could not be used, but they are simply taken off and re-applied to the anterior position. Any one who has tried this apparently complex procedure, and has seen a difficult labor change quickly into a simple one with really remarkable ease, will be glad of another opportunity to test its efficacy.

"Leopold has stated that the forceps is the bloodiest of all obstetrical operations, and this is undoubtedly true, if the child is rapidly dragged through a partially dilated birth canal by brute force. On the other hand, if properly employed, it is a means of saving instead of destroying the perineum, inasmuch as the exit of the head can be controlled more effectively by means of the forceps than by any other procedure."—(Williams).

NEWS ITEMS AND COMMENTS

BOONE—Dr. I. C. Perkins, who has been practicing at Grant, Boone county, for several years has gone to New Mexico on account of ill health.

BELL—Dr. L. D. Hoskins, who has been practicing in Pineville since January, 1910, has moved to Fowlerston, Texas, where he will make his future residence and practice his profession.

JEFFERSON—His many friends will be glad to know that Dr. Ap Morgan Vance, of Louisville, whose serious illness has been heretofore noted, is rapidly improving and will shortly resume his active work.

OLDHAM—Dr. Eleanor A. Harthill has gone to Corpus Christi, Texas, to visit her brother, Dr. Caldwell and Mrs. Caldwell. During her absence, Dr. R. B. Pryor will act as assistant secretary of the Oldham County Medical Society.

TAYLOR—Dr. Carter B. Buchanan, who since his graduation last June, has been in the U. S. Marine Hospital service, located at Chicago, Illinois, is now at home. Dr. Buchanan is with his father, Dr. J. B. Buchanan, of Campbellsville, but has not entered in the practice of his profession yet.

HOPKINS—The Hopkins County Medical Society held a joint meeting with the ministers, teachers, dentists and physicians of Hopkins county, which was done for the purpose of stimulating cooperation among the four professions.

GRAVES—The JOURNAL ANNOUNCES with regret the death of Dr. D. H. McMasters, at Pryorsburg, of dysentery.

The entire profession of the State will sympathize with Dr. George T. Fuller in the death of his little daughter, Mary, who died from a sarcoma, involving a right shoulder and arm, on March 13th.

BOYLE—Mrs. Ida Barker, of Danville, died April 18th, at her home from pellagra. This is the first death that has resulted in this portion of the state from his new disease. Mrs. Barker had lost her mind as a result of the infection, and was several days ago ordered sent to the asylum by a jury in the circuit court.

BARREN—Dr. J. W. Acton, of San Marcos, Texas, has moved to Glasgow, Ky., where he will practice his profession. He is an old resi-

dent of Lincoln county and moved from King's Mountain to Texas a year ago. We are glad to welcome him back to Kentucky, and feel certain he will make a useful member of the Barren County Medical Society.

CLARK—The doctors of this city have organized for the purpose of giving a fair, the proceeds of which will be used for the benefit of building a hospital for Winchester. The dates were fixed as August 6-10. The following are the officers: Dr. D. H. McKinley, president; Dr. E. R. Bush, first vice president; Dr. Howard Lyons, second vice president; Dr. Ernest Cole, treasurer; Mr. G. Lee Waincott, secretary.

JEFFERSON—Dr. I. N. Bloom, who has been spending the last ten days in New York and at Yale with his son, Mr. Nathan P. Bloom, has returned home.

Dr. J. T. Windell returned several days ago from New York, where he attended the meeting of the American Urological Association, held last month at the Astor House.

Dr. Thomas L. Butler and Mrs. Butler and Miss Alice Short are spending some time in New York City.

BOYD—Dr. Manley C. Warren, of Buchanan, died February 20th, at his home. He was the honorary member of his class at Jefferson Medical College and a specialist on Bright's disease.

Dr. J. A. Pritchard, of Mavity, has located at Buchanan, and is occupying the office of the late Dr. Warren.

Dr. J. C. Wheeler, of Lawrence County, has recently changed his location to Buchanan.

WOODFORD—"At the request of the Civic League the State Board of Health sent Dr. W. L. Heizer, their best sanitary inspector, to Versailles, April 17th, to look over the conditions there with a view to ascertaining the cause of the fevers, which have existed to such an abnormal degree in this community. Dr. Heizer addressed a public meeting at the court-house on Thursday, April 18th, giving the result of his investigation and suggesting a remedy for our troubles."

CARLISLE—We are exceedingly sorry to record the death of Dr. W. T. Graves, of Bardwell, who died on March 18th, at the age of 63. Dr. Graves enjoyed a large practice and the esteem of all who knew him. He was a member of his county and State societies since 1906, and took an active interest in promoting the interests of his fellow practitioners.

Dr. T. J. Marshall resigned as County Health Officer and Dr. R. T. Hocker was elected to succeed him on April 10th.

BARREN—Dr. A. T. Botts, who has been located at Cave City during the past four months has returned to Glasgow where he will practice in the future.

Dr. T. F. Miller, of Goodnight, who has been on the sick list for the past ten days, is able to be out visiting his patients again.

Owing to the inclemency of the weather and bad roads, the Barren County Medical Society has not met during the past four months but expect an interesting program for the May meeting and all during the summer months.

SCOTT—The members of the Scott County Medical Society had as their guests on April 11th, the Kentucky Midland Medical Society. This is one of the best district medical societies in the South and as usual there was a representative assembly of doctors from Central Kentucky. Dr. B. J. O'Connor, of Louisville read a paper on "Vaccine Therapy" which was discussed by Dr. E. B. Bradley, Lexington. Dr. E. C. Barlow, of Georgetown, read a paper on "The Simplest Clinical Test of Urine," discussed by Dr. S. L. Beard, of Shelbyville. "Open Treatment of Fractures" was the title of a paper by Dr. B. F. Vanmeter, of Lexington, discussed by Dr. O. H. Reynolds, Frankfort. Dr. J. A. Stuckey, of Lexington, presented a paper on the "Trained Nurse Question," discussed by Dr. U. V. Williams, Frankfort.

FAYETTE—Embodied in the report of the special committee, which went to Mont Clair, N. J., recently to investigate sanitary conditions there, which was read April 19th at the meeting of the Board of Health, were a number of recommendations, which the board hopes to apply to Lexington when it formulates its new sanitary code.

The report, which was unanimously accepted, is being put into shape for printing. The members of the special committee who went to Mont Clair were Dr. W. O. Bullock, president of the board; Dr. N. R. Simmons, Health Officer, and Dr. R. M. Allen, pure food expert.

The board recommended that the Waterworks Company, for a stated period, make a reduction from the price usually charged for tapping the water mains, in order to encourage those who have not already tapped to do so before real summer weather sets in. The Water Company has usually done this at the request of the Board of Health, and it is thought they will comply this time.

The Water Company having reported some trouble experienced by one of its inspectors on a trip of inspecting some property which lies on the watershed of the reservoir, the inspector was appointed a deputy under the

Board of Health, in order to give him authority to compel the property owners to submit to the inspection. It is probable that the county board will take similar action for the purpose of better protecting the water supply of the city.

WEBSTER—There is an epidemic of small-pox in Providence, Webster county. At the request of the county officials, Dr. Heizer, of the State Board of Health, addressed a meeting of the citizens of Providence.

BULLITT—The following notice from the Bullitt County Board of Health will be of interest:

"To the Citizens of Shepherdsville and Bullitt County.

"Owing to the prevalence of cerebro-spinal meningitis and other infectious and contagious diseases in Jefferson and adjoining counties, we take this means of calling the attention of the people to the necessity of cleaning and disinfecting their premises. This, as well as most all other contagious diseases, has its origin in dirt, dust and filth, and the removal of this matter does away with the breeding grounds of the germs and thus puts the only effective check on disease. The State Board of Health is demanding that the people, especially in the small towns, take steps at once to place their premises in a sanitary condition. To do this it is imperative that you remove all accumulations of garbage, decaying animal and vegetable matter, and especially the off fall from barns, stables and hog pens, as these are the special breeding places of the ever present house fly and it has been proven that one of these fellows can carry enough typhoid fever germs on his feet to infect an army. Screen your houses to keep him away from the food you eat, but do away with his birth place and you have ended his career more effectively. The orders of the board are that this cleaning up must be done by April 20th and those who refuse or neglect to attend to this matter by that date will have to be proceeded against according to law. This is to your own advantage and not your neighbor's and may save you much in more ways than dollars and cents. Clean up. Clean out. Keep clean. Remember that dirt, dirth and the Devil are your personal enemies.

"Bullitt County Board of Health,

"Dr. G. W. Kirk, Chairman,

"Dr. S. W. Bates, Secretary."

FAVETTE—Lectures, demonstrations and special exercises calculated to impress upon both teachers and pupils the importance of sanitation and hygiene in the schools, as well as in daily life, were the features of "Health

Day" which was observed April 15th, in all the public schools of Lexington.

Superintendent M. A. Cassidy and Dr. C. L. Redmon, Health Inspector for the Lexington schools, visited every school in the city during the day and at each school gave helpful talks on hygiene and sanitation, which in many instances were supplemented by special exercises, consisting of talks by the teachers, recitations, readable articles and demonstrations intended to impress the necessity of personal cleanliness, health rules, ventilation and care of the school rooms and premises where the children spend so much of their time.

At Dudley School, of which Mrs. Milford White is principal, there was an especially interesting program, in which teachers and pupils took part.

The movement to have the school children observe sanitary regulations and health laws has been very successful in other cities, notably in Cincinnati, where last year a campaign was waged which resulted in the formation of a league, whose work was evidenced in cleaner and more sanitary school rooms and grounds and in impressing upon all the spirit of the "City Beautiful."

The city health authorities everywhere have encouraged this movement, and much good is expected to result from it here in Lexington.

Later there will be a general cleaning up day, and the idea gained by the children from the talks, demonstrations and exercises of "Health Day" will be given a practical test.

KENTON—The Kenton County Anti-tuberculosis League held a special meeting on April 13th, at the residence of Harry B. Mackey to perfect the organization, the first meeting of which was held two weeks ago. It is the intention of the league to enlist the interest of every church, fraternal order, club and organization in Kenton county, so that in the end they expect to have at least 350 members.

A campaign of education will be started at once. Lecturers will be brought to Covington, and they will endeavor to show that tuberculosis is positively a preventable disease by proper living. A nurse was also engaged, and she will make daily talks to the classes of all schools and distribute literature.

One of the most important features of the organization will be the free dispensary, which will be opened May 1. The following prominent physicians will be in charge: Dr. J. R. Meek (Chairman), Dr. Tebbbs Raushaw, Dr. H. F. Wilson, Dr. R. W. Bledsoe, Dr. Charles Reynolds, Dr. Cliff Harris, Dr. E. N. Estes, Dr. Steve Sharp, Dr. James Ryan, Dr. F. G. Adams, Dr. Henry C. White, Dr. B. F. Menifee and Dr. H. P. Martin.

There will also be a medical council, to be appointed by Dr. J. T. Wallingford, who will

be Chairman. The free dispensary will be divided as follows: Four days and one evening will be given to the treatment of tuberculosis; one day to eye, ear, nose and throat; one day to surgery, and one day to general medicine.

The following permanent committees were appointed: Executive, W. W. Brown, Rev. Jas. T. Gorey, E. T. Gale, H. P. Colville, H. B. Mackoy, Alex. Klein; press and publicity, E. T. Gale, (Chairman), James Young, W. S. Groom, Dr. Meek; committee on finance, H. B. Mackoy (chairman), F. J. Hermes, W. W. Brown, W. N. Hind, C. A. J. Walker.

Most enthusiastic work will be started at once to organize Flag Day, which will be in six or seven weeks. Considering the importance of the fight against the white plague, the league is confident that it will easily raise \$5,000, as it will require fully that much money to carry out their plans.

FRANKLIN—Dr. Albert Stuart, of Staumoping Ground, Scott County, has recently moved to Frankfort, where he will practice his profession. He was a member of the Scott County Medical Society for several years and did much for that society and we feel sure he will be an addition to the Franklin County Medical Society.

JEFFERSON—B. Morgan Vance, son of Dr. Ap Morgan Vance, who is at present taking a medical course at the University of Pennsylvania, has been notified of his appointment as resident pathologist at Bellevue Hospital, New York City, for five years, beginning July 1 next. He will complete his studies at the University of Pennsylvania in June and will then take up his new duties. Young Vance was substitute interne at Bellevue last summer during his vacation. He is a graduate of the Louisville Male High School.

JEFFERSON—The old South Park Hotel, situated on an elevation in Jefferson county, eight miles beyond the city limits, on the line of the Louisville & Nashville Railroad Company, has been leased for a long term of years to Dr. E. G. Dick, resident physician at a Crab Orchard, (Ky.) institution. Dr. Dick plans to convert the building into a sanatorium for inebriates, to be opened on or about June 1.

The lease on the property was given by W. H. Harrison, of this city, the present owner. It contains a clause which gives Dr. Dick the right to purchase within a certain time after the date of expiration.

The hotel building once was popular as a summer resort, but has been closed for some time. It is three stories in height and con-

tains fifty-six rooms. Dr. Dick is at Brooks Station with his daughter, but will be present in a few days to direct improvements on the structure.

COUNTY SOCIETY REPORTS

Carlisle—The Carlisle County Medical Society met at Bardwell, March 19th, in call meeting and by unanimous vote a petition was sent Governor McCreary asking him to veto Senate bill No. 56. Members present, Drs. Payne, Dunn, Marshall, Crouch, Jackson, Lankin, Wm. Mosby. That being the only business the society adjourned.

J. F. DUNN, Secretary.

Christian—The Christian County Medical Society met in regular session March 19th, in the City Court Room, Hopkinsville.

Those present were: J. L. Barker, H. F. Bassett, J. W. Harned, Austin Bell, W. A. Haynes, J. Paul Keith, J. H. Rice, G. W. Laey, F. M. Stites, B. B. Roach, G. L. Gates, W. W. Durham, W. M. Bassett, W. A. Laekey, D. H. Erskintian, W. H. Watts, J. B. Jackson and W. S. Sandbach.

After the reading of the minutes of the last meeting, the President called for report of cases. There was several reported and fully discussed.

On motion of the Secretary, and seconded by Dr. Stites, the society passed resolutions condemning the Senate bill No. 56, and requested the Governor to veto same. The Secretary was instructed to write said resolution and mail to the Governor with a list of the members of the society.

W. W. Durham read a paper on "Diagnosis and Treatment of Diphtheria." This was one of the best papers of the year, and brought forth a discussion from every one present. The essayist emphasized the importance of using antitoxin in all doubtful cases and in large doses.

J. W. Harned quizzed the society for some time on "Prostatic Hypertrophy." This was our first quiz, and the Quizmaster proved himself "on the job." He brought back memories of school days which we all enjoyed.

W. W. Durham presented a very interesting clinic and the society went to the office of Drs. Keith and Jackson, where an X-ray photo of the tumor was made. The diagnosis was suspected and an exploratory operation was advised.

No further business was adjourned to meet the third Tuesday in April.

W. S. SANDBACH, Secretary.

Daviess—The Daviess County Medical Society met at the City Hall, Owensboro, on March 19th, with the president, W. E. Irvin, in the chair and thirty members present. As suggested in a com-

nuniation by our State Secretary, a committee was appointed to write our congressman urging him to use his influence to have a committee on Public Health appointed.

J. R. McGary read a paper on the "Use of Salvarsan in the Treatment of Syphilis." It was discussed by P. D. Killim, C. H. Todd, J. W. Barnhill, A. McKenney, W. F. Strimon, W. E. Irvin, D. M. Griffith, W. H. Strother, J. Glahn, S. J. Harris.

All agreed that when properly given in well-selected cases it produced good, sometimes wonderful and even magic results.

As to the mode of administering it, none used the subcutaneous method; most of them used the intra-muscular mode. In this way all said the alkaline solution caused too much pain and reaction; while the neutral suspension was sometimes, though rarely, not absorbed, and then caused local trouble. The essayist said he had used the intra-venous method, and considered it the ideal, but death had been known to follow such administrations.

J. L. Carter read a paper on the "Static Induced Current in the Treatment of Rheumatism." He went into the etiology of rheumatism, and told why this current would relieve it. His paper was discussed by I. J. Hoover, S. J. Harris, H. P. Bean, and others, and by the essayist in closing.

J. D. Roberts read a very interesting paper on "Pneumonia," which was discussed by M. A. McDonald, S. J. Harris and others.

J. J. RODMAN, Secretary.

Henry—The Henry County Medical Society met at the office of the Secretary on March 25th, at two o'clock p. m., meeting called to order by Alfred Waincott, President. Those present were: W. B. Oldham, W. L. Nuttall, O. P. Chapman, Everett Morris and Owen Carroll.

A. P. Dowden reported a case of appendicitis, operation with recovery, he also reported a case of stone in the bladder.

Owen Carroll reported a case of "Cerebro-Spinal Meningitis. Serum administered and prospect for recovery bright.

Everett Morris read a paper on "Diagnosis of Incipient Tuberculosis. A. P. Dowden opened the discussion.

The society unanimously recommended to the Governor the appointment of Everett Morris on the Tuberculosis Commission.

Meeting adjourned to meet April 29th, at 2 p. m.

OWEN CARROLL, Secretary.

Hopkins—At a meeting of the Hopkins County Medical Society held at the Young Men's Christian Association building, at Madisonville, at 10 o'clock in the forenoon, on Saturday, April 6th, 1912, the following proceedings were had:

The meeting was called to order by President

Eldred A. Davis, of Earlington, who made a few preliminary remarks regarding the purpose of the meeting, and called on Rev. W. J. Mahoney, of Madisonville, to invoke the blessing of the Deity.

The meeting then proceeded with the rendering of its program and Rev. W. J. Mahoney, being first on said program, addressed the audience on the subject heretofore assigned him, "The Relative Duty of the Ministers."

Prof. C. E. Dudley, of Earlington, next addressed the meeting upon "The Relative Duty of the Teacher," his opening remarks being as follows:

"Mr. Chairman, and I am glad to say: Ladies and Gentlemen, it is with pleasure that I am permitted to be present at this meeting and lend my mite to the program, I feel though that the mite will be small indeed.

I present a short paper, not with the idea that it will be exhaustive, but suggestive, which I will be pleased to hear discussed by you gentlemen who are better informed.

We have just heard a very excellent talk on the relative duty of the pulpit and medical profession, and we are to correlate with these two the duty of the Teacher.

I believe the teacher brings nearly everyone in touch with the work as completely as any one profession, because of the fact that gathered into our public schools are the children of all the families of the entire community; it is through this school that the future of the community is to be governed, consequently we are all interested along these various lines."

He then proceeded to read a paper prepared on this subject, which will appear in the Journal.

E. B. Hardin, of Madisonville, was called upon to present his views on "The Relative Duty of the Dentist." And after a few preliminary remarks as to the degree of delicious pleasure it afforded him to do so, he read a very interesting paper on the above subject.

L. E. Nichols, of Nebo, then addressed the meeting in a most masterful and exhaustive manner on the "Relative Duty of the Physician."

After completion of Dr. Nichols' address, the President of the meeting announced that the meeting was opened for a general discussion of the various subjects that had been so ably handled by those to whom same had been assigned, and called for voluntary and impromptu addresses by the representatives of the various professions present at the meeting.

D. W. Davis, of Morton's Gap, was the first to respond as follows:

"There is nothing for me to add to these papers that have been read, but I want to say that I am glad to know that some of the teachers and preachers are beginning to appreciate what the doctors have had to contend with and are willing to get in the harness and pull with them and re-

operate in every way, further than that I have nothing to say."

I. T. Townes, of Madisonville, said: "Mr. President, I cannot add anything to what has been said, but I want to compliment those who have rendered such excellent papers and have so well performed their part of the program. This is a very important subject, and should be discussed and studied by the various professions and a plan made by which we can benefit our society and our schools, and I would like to hear someone who can speak get up and tell what we can do to help us out. I just want to compliment again these men and those who come and are interested in this meeting and hope that they will help us by coming out again."

J. L. Watkins, Y. M. C. A. Secretary of Madisonville, spoke as follows: "Mr. President, I am very glad to have been able to hear these excellent papers and addresses; I am here representing the Y. M. C. A., and assure you that I am interested in all four of the branches discussed by the representative professions, and take this opportunity of welcoming you to this building for your future meetings and assure you that the next time you come this room will be more inviting, and will be equipped with better furnishings, etc., and want you people to feel welcome."

President: I desire to thank you very kindly on behalf of the society."

Prof. C. E. Dudley: "I might add a word to what I have already said. Two or three things have interested me very much, along the line of defectiveness in the physical condition of pupils in their school work; I notice that the doctors take a great deal of credit on themselves, then comes the ministry and claim to be the whole show, and somehow I have been teaching so long I have gotten it in to my mind that we teachers are the foundation to the whole thing, and when you take up the matter of public health, you will have to come back to the school."

As a teaching profession, most of us get in so easy that we do not represent very much, but through us there is a great deal to be accomplished. It is surprising to know what a loss there is to the State of Kentucky through defectiveness and how many pupils there are in the schools that are in urgent need of a medical examination. I venture that you get very few calls to make an examination of a child to see if it might be improved physically in order to develop it mentally; the tendency is not to call in the doctor until the child gets down sick. Parents are blinded to the physical and mental welfare of their children.

The figures quoted by the last speaker regarding the defects in the hearing, sight and breathing organs of school children, quoting the statistics, are really startling, yet I can see that these conditions are duplicated in my own school at Earlington. If you will look for theme you will find them. What is the remedy? How are we to help the public along this line? I am glad that this

subject is popular among the medical fraternity and trust we can suggest some plan to aid the public in meeting this most important issue. I believe that the medical fraternity with the help of the teachers can accomplish wonders in conducting to the public health as well as to the public wealth. The teachers are generally ignorant along these lines, we find a few that are informed along these lines, then we find a great many that do not know anything, and it will take the medical fraternity to educate our teaching fraternity up to the correct method of carrying out hygienic principles."

Prof. R. B. Rubins, Superintendent of Madisonville Public Schools: "Mr. President, Ladies and Gentlemen: I regret that business matters did not permit me to hear the various papers and discussions of this question that I am intensely interested in, but think I have been here long enough to grasp the idea that you are all working on, I heard a greater part of Dr. Nichol's address which was most gratifying."

It occurs to me that like every other reform, the matter of education, the matter of training the mind has had its stages of development, just like the matter of public health had its development. Heretofore the matter of public health had been largely an individual matter, every man his own master, and looking out for those things which menaced the health of his immediate family, and not take a general view of improving the conditions, or that anybody else was responsible for the physical condition of anybody else; as all reforms, it has become centrally taught that everybody else is responsible for the condition of everybody else. A few years ago there was no precaution against contagion, a man with a contagious disease was turned loose whenever he wanted to be, and nothing particularly was thought of it; that is not true among men of the medical profession to-day I am glad to say, because they know that will not do, but a few years ago that was more or less the case.

Now as far as the school is concerned, I am like Prof. Dudley, the teaching profession will have to be educated by the medical fraternity along this line. The public also will have to be educated to the great need of sanitary conditions. You will be surprised to know of the difficulty we had in our schools here in introducing the sanitary drinking cups in the school. We have to work diligently to see that it is observed, and although it is a very simple matter.

Now the thing that impresses me most of all is this, how are we going to work together on the proposition, the medical profession, the ministry and the teaching profession, are the ones to start this revolution against unsanitary conditions, and we should get together on it and outline some plan whereby we can make our work count, there is no telling what good we can do. The public must be brought to see this thing in a proper light, the work that the school does in

causing the child to observe the individual drinking cup is crippled by the child going to a public gathering where there is an old filthy tub with a row of dippers hanging on the side; we say at school that you must ventilate and free the room of bad air, then they will go to church and sit for two hours in a stuffy close room where the air is very bad, the preacher will sweat and everybody else will sweat and no one get the benefit out of the sermon that they should and would under more favorable conditions.

I believe that we should have medical inspection in the schools.—I have been talking about it to Dr. Sory, and I can see a possibility in it; I believe if the medical profession are as interested as we are,—and they seem so to-day,—and if they are willing to do as much along these lines as we do without pay, that we will have it in the schools by next fall.

We cannot wait on the reactionaries, we have got to take the reins in our own hands. Let's get busy and do it; I am for it."

E. B. Hardin: "Excuse me for getting back on the floor, but I wish to compliment the other members on their splendid papers, where I am only a member of the dental profession, I want to do all I can to further the education of the public to the needs of sanitation; the dentist profession claims to be an heir of the medical profession and should assist them in bringing about improved conditions in furtherance of public health. I believe we should hold public meetings at the court house and churches and invite everyone; the time is not coming, it has already arrived, this drinking cup proposition is only one item, and the time has arrived when we as a community should arise as a whole and become enthusiasts in the work. So I suggest that we have open meetings and invite the public to participate in the meetings in general."

A. O. Sisk, Earlinton: "Mr. President and Ladies and Gentlemen: I have enjoyed these papers and discussions very much indeed; I wish to say that this was intended to be an open and public meeting and the public was invited to attend this meeting, and we are glad to see a few here, wish there was more.

When this meeting was gotten up by the physicians for the benefit of the public health, it was not at all fostered by the idea of getting jobs in inspecting schools, etc. You will find the physician at all times ready and willing to co-operate in this work. I think every school in the county should have a medical inspector.

Now these teachers can recognize defects in the pupils earlier than anyone else, and the teacher wants to know the nature of these defects and how they are to be remedied, the physician must then come in and help him remedy these conditions; the teacher often recognizes defects before the family or physician; for the physician is never called in until the child is sick.

The object of this meeting was to attempt to

bring about some co-operation between these four great professions; to discuss ways and means as to what is the best thing to do towards preserving the child's life and health and towards preventing the spread of contagious disease; and to arouse the physicians, teachers and preachers to their duty along this line, for I believe we are asleep, as evidenced by the absence of all four professions here this morning, and we must get busy and do something.

E. A. Davis: "I wish to say in regard to what Prof. Rubins has said, that as far as I am concerned individually, and believe each member of the society would be willing to give his services free in this work, if the teacher will prevail on the legislative body to provide some means to part into force the things we recommend."

I. J. Townes: "Mr. President, do you know whether or not a committee has been appointed, consisting of a teacher, preacher and doctor, or two of each, to see into this matter?"

President: There has not.

I. J. Townes: "How would it do to appoint somebody to see into this, so as to have things ready in a definite shape to look after this matter?"

President: "As I take it the doctor proposes that we select a committee composed of a member of the four professions represented here to-day, to outline some program of public health, that sounds like a good suggestion to me, probably some one can suggest a plan that we can get together on to enforce medical inspection in the schools and improve on general conditions in preserving the public health. I will be glad to do anything I can along this line."

I. J. Townes: "Dr. Sory is our city physician and we would like to hear a suggestion from him,—would like to suggest that he be appointed physician in charge of this town,—and this being the center of the county, it will be the headquarters of the attack we are going to make. I will speak for the medical profession then, and suggest we use Dr. Sory."

President: "Let us have some kind of motion along that line."

A. O. Sisk: "Mr. President, I believe this meeting is merely an advisory meeting, more for the purpose of devising ways and means and discussing them in order to get the professions together and believe the present procedure is out of order."

I. J. Townes: "If that is out of order, how are we going to get started? If we are going to have a meeting this time and quit, nothing will be accomplished. I believe there should be something done, what do you propose?"

A. O. Sisk: "You misunderstood me Doctor, I say name a committee to do this, is that your idea in suggesting Dr. Sory?"

I. J. Townes: "My idea is to have four on the committee, four of the professions represented here, and have the committee tell us what to do."

J. D. Sory, of Madisonville, said: "Mr. President, I have enjoyed the meeting very much and really did not want to say anything, but just listen, but in the way of suggesting, I would like to say this: I think this meeting will accomplish a great deal of good, because it will get the teachers, preachers, dentists and physicians to working in harmony. I suggest that we have another meeting later on in the season, it is no question that our non-attendance here to-day is on account of the unusually bad roads in the county. Have another meeting later on in the season and have the four professions take part in that meeting. Would suggest that we adopt Dr. Townes' suggestion and have a representative committee appointed to arrange for a program for the next meeting."

I certainly appreciate the position of Prof. Rubins, as I have noticed the method he has been using in his schools in the city, and when it is necessary to have them inspected he has done so, and as a result we have had very little contagion in the schools this winter. I think we should appoint a committee to look after this next meeting."

President: "Dr. put that in a form of a motion."

J. D. Sory: "I make a motion that you appoint a committee composed of one of each profession here to-day, one minister, one doctor, one teacher and one dentist, as a Committee of Four, to arrange a program, and fix a time and place for the next meeting."

E. A. Davis: "I second that motion."

President: "Moved and seconded, all in favor of that motion let it be known by saying 'aye.'"

Chorus: "Aye."

President: "Opposed 'No.' The ayes have it, and I will appoint a committee composed of Prof. Rubins, Dr. A. F. Finley, Rev. W. J. Mahoney and Dr. E. B. Hardin, to arrange a program, time and place for next meeting. Any further business to come before the house?"

A. F. Finley, of Isley: "Mr. President, if I am not out of order, I would like to say a word or so. I have enjoyed this discussion very much. I got in late and did not hear all the speeches; I heard part of Dr. Nichols' and certainly enjoyed it, I think this meeting is stimulated, and should be called a public health revival, just a revival with us anyway. Am glad indeed to see the representatives of other professions here. If they would do as much along this line as we do, we could accomplish quite a great deal; we have done without pay more than any other profession in furthering general sanitary conditions and preserving the public health. As individuals we can do little, but as an organization we can march on."

L. E. Nichols: "I desire to thank the gentlemen who have complimented me and desire to praise the papers of the other members on the program. We have started a large work here to-day, and

we have got to work and work hard to accomplish anything; of course we cannot accomplish it all in the present generation either, but can make conditions look brighter for our children and our children's children."

I believe this work can be better accomplished by public meetings like this one started this morning; we can better tell just how many and when to have them as we go further into the work and have bigger crowds and more interest. I again wish to compliment these gentlemen on their excellent papers."

J. D. Sory: "I notice behind me another profession which we cannot afford to pass over, and that is the trained nurse, the guardian angel of the sick room, and I do not know of any profession that can be more helpful to the other four than the trained nurse. For we are only in the sick room for 15 or 20 minutes at a time to leave instructions for the nurse to carry out, for she is there all the time, and they can accomplish a great work, so I would like to suggest that the name of Miss Biatt be placed on that committee as a representative of her profession."

Miss Biatt: "Mr. President, I appreciate the honor very much, but will have to decline, as I am preparing to leave this county soon and go to my home in Washington."

Rev. W. J. Mahoney: "I want to say a word or two along the line of Prof. Rubins' remarks about these sanitary conditions. The methods he is employing in improving these conditions has come under by observation of my own children, regarding individual drinking cups and ventilation. It is the truth that we are confronted with unsanitary conditions in our churches, Y. M. C. A.'s, and all public places, with the public drinking cup. I want to say right here that the physician can do quite a bit of missionary work in the church which I do not dare bring out too strong, and that is the common drinking cup being used in the service of the Lord's Supper, they shrink when you tell them about individual drinking cups and say you are departing from the common cup as emblematical of the cup used by Christ, not taking into consideration that we have departed from the common cup when we use two cups, and we might as well have two hundred as two, there is great danger of infection from the cup passing from mouth to mouth, all sorts of danger from nasal, tongue, throat and bronchial infection, a great many people assigning a reason for not wanting the individual cups, that they rely on providential protection, and I hope you physicians will suggest some relief for this state of affairs. I want to assure you that I appreciate any relationship with each one and everyone of you and assure you that anything that lays in my power I will gladly do to help the prevailing conditions and clean up the community."

President: "I desire to thank each one of you for your part in the program and all who have so promptly responded in these discussions and as

sure you of our appreciation of your splendid efforts. Now if there is nothing further to come before the meeting, we will stand adjourned."

A. O. SISK, Secretary.

Lincoln—The Lincoln County Medical Society met in Dr. Peyton's office, April the 16th, with the following members present: Drs. O'Bannon, Childers, Jones, Brown, Peyton, Carpenter, Harmon and Phillips.

E. J. Brown read a very interesting paper and presented some clinical specimens that made this an interesting meeting.

Our next meeting will be held at Hustonville, the third Tuesday in June. Drs. Singleton, Jones and Childers will read papers and we look forward to this meeting with a great deal of pleasure.

M. M. PHILLIPS, Secretary.

Ohio—The Ohio County Medical Society met in S. D. Taylor's office, Beaver Dam, Thursday afternoon, April 4th, at 1:30 p. m. Members present: J. O. McKenney, J. S. Smith, F. B. DeWitt, E. W. Ford, J. W. Taylor, S. D. Taylor and Oscar Allen.

The meeting was called to order by Dr. J. W. Taylor, the president, minutes of the last meeting were read and approved. Applications of F. B. DeWitt, Willard Lake and E. B. Pendleton were reported favorably by the Board of Censors and they were elected to membership. J. A. Duff's application was presented and referred to the Board of Censors.

J. W. Taylor presented a case of "Pterygium."

S. D. Taylor reported a case of "Imperforate Hymen," diagnosed only after a most thorough and painstaking examination during the menstrual flow. An examination in the interim having led to a diagnosis of a possible atresia of the vagina and was so reported at our last meeting. This case was one of extreme interest on account of its rather infrequent occurrence, its difficult diagnosis and the predicament the young lady was in by being engaged to be married in the near future. On account of this latter fact and the extreme smallness of her pelvis it was deemed best to render her sterile, which was done.

J. O. McKenney presented a case in which he had given the tuberculin test showing a mild reaction.

E. W. Ford reported a case of stragulated hernia in which was found a considerable amount of what later proved to be popcorn.

S. D. Taylor read a most interesting paper on "Serum and Vaccine Treatment," which was discussed by J. S. Smith, J. D. Taylor and J. O. McKenney.

J. O. McKenney presented a very interesting paper on the "Early Diagnosis of Tuberculosis," in which he emphasized the value of the tuberculin test and the importance of a more thorough

study of this disease by the physician. Discussion by DeWitt, E. W. Ford and J. S. Smith.

A motion was made and seconded that we meet again at Beaver Dam, Thursday afternoon, May 2nd, at 1:30 o'clock.

E. W. Ford, who intends to take the three weeks course, offered by the Chicago Polyclinic during April, very kindly consented to give us a paper at our next meeting on "Some Things Learned in Chicago."

Adjourned to meet May 2, at 1:30 p. m.

OSCAR ALLEN, Secretary.

Meade—The Meade County Medical Society held its regular monthly meeting at Brandenburg, March 28th, 1912, at 9 a. m.

A. A. Baxter read a very interesting and instructive paper on "Pneumonia."

T. H. Hardesty read a paper on "Influenza," which was sent to the Journal for publication.

All the essays were thoroughly discussed and the meeting was highly successful.

No further business the society adjourned.

E. C. HARTMAN, Secretary.

Muldraugh Hill—The Muldraugh Hill Medical Society met in the City Hall in Elizabethtown at 10:30 a. m., with Dr. Ed Smith, President, in the chair in the absence of the Secretary, Gaylord C. Hall, on motion Hugh D. Rodman was elected Secretary pro tem. The presentation of clinical cases and specimens was passed over for the present. On motion of Dr. McChord the program was changed so as to permit Dr. C. B. Spalding to read his paper first instead of last as he, Spalding, wished to return to Louisville on the next train.

C. B. Spalding read an excellent paper on the "Urethra," and demonstrated it by some pathological specimens, which made it all the more interesting. I am sorry that I cannot present the paper with this report, but he has promised that we shall have it. This paper was discussed at length by Drs. McChord and Willmoth and in closing Dr. Spalding brought out a new point in reference to gonorrhea, which he said was regarded by many people, and some doctors as a trivial disease. This he said is a great error; gonorrhea was at all times a serious disease and demanded our greatest skill and careful attention, and that we should be sure our patient was entirely well before we discharged him.

C. T. Riggs, of Upton, reported a case of splenomegaly, which had been treated by regulars, osteopaths and finally by Charlie Whitteason and was relieved by death.

W. E. Rodman, of Hodgenville, was down for a report of case of "Placenta Previa." In his absence Dr. Ed Smith, who had seen the case in consultation, was, on motion, invited to report the case, which was a case of placenta previa centralis, and had, before the arrival, lost a large quantity of blood and was very weak and anemic, was supposed to be five months pregnant. A

speedy delivery was made of a very small living child, which was wrapped in cotton and kept so for weeks, and was fed regularly and lived and is now five years old and of an average size. The mother made a slow but perfect recovery and is also still living. Dr. Smith did not believe that this woman was more than five months pregnant and at first had no hope of the child living, but after attending to the mother, they found the baby still living and gave it immediate attention with the result reported.

Hon. James Montgomery, who is an honorary member, brought permission to report a case along this line. The child which was premature after a slow and tedious delivery weighed only 1 1-2 pounds, but lived to be grown.

A. D. Willmoth reported a case of "Tubercular Pleurisy," which report is herewith submitted, and was discussed by several members.

C. T. Riggs read a good essay on "Lobar Pneumonia," which is herewith attached, which was discussed by Hubbs, Thornton, Rodman, And and Ravitch, and Dr. Riggs in closing.

On motion of Dr. Willmoth, Drs. Adams, McChord, Willis and And were appointed a committee to draft a suitable memorial on the life and character of Dr. D. C. Bowen, deceased, and report at the next meeting of this society.

G. G. Thornton spoke feelingly on the life and character of Dr. Bowen, both as a man and a physician. On motion of Dr. Riggs the society adjourned for five minutes out of respect for Dr. Bowen.

M. L. Ravitch read an excellent paper on "Toilet Infection," which I am sorry that I cannot furnish you, but he has promised it to us.

M. W. Steele read a most interesting and instructive paper on "Pellagra," which will accompany this report, and which was freely discussed by Ravitch, Rodman, Willmoth, Riggs and McChord and Steele in closing.

E. L. Gowdy read a most practical paper on "The Causes and Treatment of Convulsions in Infancy and Childhood," which was discussed by Rodman, Thornton and Riggs, and which will accompany this report.

Thus an interesting program was closed, all of which was rendered except Dr. Gaddy and Dr. Rodman, of Hodgenville, whose absence was greatly regretted.

After an informal talk adjourned to meet the second Thursday in August.

HUGH D. RODMAN, Secretary.

Taylor—The Taylor County Medical Society met in the office of the Secretary. Present: Drs. Gowdy, Buchanan, O. M. Kelsay, S. H. Kelsay, Black, Reesor, Elrol and Atkinson.

Minutes of meeting of December 7, 1911, read and approved. At that meeting, which was the date for the election of officers, so many of the members were called away during the meeting that the election of officers was deferred till the

first meeting of this year. The Taylor County Society hibernates during the months of January, February and March of each year so this was the first meeting of the year.

On motion of Dr. Reesor, seconded by Dr. Black that the old officers be re-elected for the year 1912. Motion prevailed. The officers now stand: President, E. L. Gowdy, Vice President, Dr. Murphy; Secretary Treasurer J. L. Atkinson; Delegate, Dr. Reesor.

E. L. Gowdy made further report on case of "Pellagra," that the symptoms all subsided in the late fall and now patient is apparently in usual health. Also reported that the thought patient is taking an advertised treatment at \$5.00 per bottle.

E. L. Gowdy read a paper on "Causes and Treatment of Convulsions in Infancy and Childhood." This was a splendid paper and was prepared for the meeting of the Muldraugh Hill Medical Society the next week. The discussion of the paper was highly commendatory. In closing he emphasized the contraindication of emetics. Also the necessity for care in administering depressing drugs, such as chloral, in convulsions ushering in acute diseases.

J. L. ATKINSON, Secretary.

Wolfe—The Wolfe County Medical Society met in the office of B. D. Cox on April 5th, 1912, and elected the following officers:

W. T. Center, President; W. H. Hobbs, Vice President; B. D. Cox, Secretary and Treasurer.

I. A. Shirley was present and gave us a splendid talk on organization and "Hookworm" and entertained a large crowd at the court house at night.

A committee was appointed and a program was arranged for our May meeting.

The meeting then adjourned.

B. D. COX, Secretary.

Spontaneous Rupture of the Spleen in Typhoid.—Melchoir has found fifty-six articles on this subject but only thirteen authentic cases on record. Signs of intraperitoneal hemorrhage should suggest spontaneous rupture, especially if the spleen is much enlarged, and it should be exposed at once and removed. Getting up too early is dangerous on this account if the spleen is much enlarged, especially if it enlarged very fast.

Diagnosis of Air Above Pleuritic Effusion.—Kraus calls attention to the instructive findings with roentgenoscopy when the patient is examined erect and then with the trunk inclined at an angle of about forty-five degrees. As the trunk is thus bent over, a clear space is seen above the level of the fluid, while in the erect position there is nothing to show the presence of the spontaneous pneumothorax. It springs into view on the screen as the level of the fluid shifts.

BOOK REVIEWS

Illustrated Catalogue.—W. B. Saunders Company have just issued a new (16th) edition of their Illustrated Catalogue which describes some forty new books and new editions published by them since the issuance of the former edition.

The books listed in this catalogue cover every subject of interest to the medical man. The descriptions and illustrations are such as to enable the reader to select easily just the book he wishes on any branch. It is really an index to correct medical literature—an index by which the practitioner, the surgeon, and the specialist can acquaint himself with what is new in the literature of his subject.

This edition also contains an illustration and description of Saunders' new building, now being erected on Washington Square, Philadelphia's new publishing center.

Any physician wishing a copy of this handsome catalogue can obtain one free by addressing W. B. Saunders Company, 925 Walnut Street, Philadelphia.

"Case Histories in Medicine" by Dr. Richard C. Cabot. Published by W. M. Leonard, Boston, Price \$3.00.

An exceedingly interesting presentation of case histories under the headings of Infectious Diseases, Diseases of the Gastro-Intestinal and Biliary Tract, Diseases of the Urinary Tract, Diseases of the Circulation, the Respiratory System, etc. The introduction of a series of pertinent questions and answers with many of the cases carries one into the hospital ward and is equivalent to a clinical lecture. This, under so capable an instructor as Dr. Cabot, makes the collection of cases of great value to the thinking physician and constitutes a post-graduate course at home.

The Surgical Clinics of John B. Murphy. M. D., at Mercy Hospital, Chicago, Volume I. Number 1. Octavo of 133 pages, illustrated. Philadelphia and London: W. B. Saunders Company, Publishers, 1912. Published Bi-Monthly. Price per year: Paper \$8.00 Cloth, \$12.00.

This volume represents a series of verbatim reports of Dr. Murphy's talks edited but slightly, more to avoid repetition than to enlarge the scope of the topic discussed.

The history of each case is given, then follows the comments of Dr. Murphy covering the technique of the operation, the diagnosis, the methods of arriving at the same, and all the points involved in the living pathology of the particular type of case.

The subjects are varied; tumors in various locations, varicoele, salvarsan, fracture of the patella, blood clot in bladder and tuberculous of the kidney, Charcot's disease of the hip joint, nerve anastomosis, duodenal ulcer, hemangioma of the

leg, fistula in ano, and others, are placed before us, diagnosed, treated and discussed generally.

IN MEMORIAM, DR. JOHN MASON KASH.

Failing to see the report of the death of one of our county members, by our secretary, I wish to report the death of Dr. John Mason Kash, the President of the Breathitt County Medical Society, and one of the oldest active practitioners in Eastern Kentucky. He graduated at the Kentucky School of Medicine in 1888, and has been in active practice for fifty years, doing an extensive practice and up to within one month of his death, which occurred while he was visiting his daughter, January 30th. He was a Christian gentleman and an exemplary citizen, always holding up the bright side of life and was quite a factor for good in his community, raised a large and highly respected family, all of whom survive him, except his son, Dr. Silas Kash. Very few men live to do fifty years of very active practice and do the very hard work which a mountain doctor has to do. He was seventy-five years old and had been afflicted with Bright's disease several years but was never but what he could attend to his practice until three or four weeks of his death.

O. H. SWANGO.

Disease of the Optic Nerve and Retina Connected with Pregnancy.

—Dolganoff insists that when the pregnancy alone is responsible for the ocular disturbances, expectant treatment should be the rule, and he reports a case in which a young woman had suddenly become almost totally blind in the third and fourth months of her first pregnancy. Except for recurring headache she seemed otherwise healthy. She was kept in bed and given dry sweats and hot baths every two or three days, with iodine, and improvement gradually followed. The assumption seems plausible that some toxic substances were produced during the first months of the pregnancy and that they had some special affinity for the optic nerve. Later the organism adapted itself to the condition, possibly aided in this by the treatment adopted, and in the course of the next two or three months all the functioning and exerting apparatus came into good working order and all disturbances subsided. The case teaches that when an internist, gynecologist, syphilologist and neurologist—all these specialists were consulted in this case—can find nothing to explain the optic neuritis or retinitis, the trouble can be ascribed to the pregnancy alone and probably, can be safely left to time.

TONSILLITIS.

By C. L. NICHOLS, Louisville.

While acute inflammations of the gland in general possess characteristics of greater or less similarity the one to the other, the symptoms being quite uniform, it is, nevertheless, important to understand what symptoms are common to all cases, and what indications they offer for treatment, and also to appreciate the special conditions and needs which may exist in the given case.

Tonsillitis may be divided into 1st, simple or superficial, acute, sub-acute or chronic, 2nd, Follicular, 3rd, Parenchymatous, 4th, Tonsillitis with abscess in the substance of the gland (quinsy), 5th, Peri or retrotonsillar abscess.

Follicular tonsillitis may be divided into simple or catarrhal, and the diphtheritic forms. The diphtheritic variety should not properly be classified with follicular tonsillitis at all, since the disease must in reality be either distinctly diphtheria or distinctly non-diphtheritic; yet, there are so many cases which to all appearances, occupy an intermediate position between the two, that diagnosis becomes difficult, and the disease is worthy of consideration.

ETIOLOGY.

The causes of tonsillitis may be divided into predisposing and exciting. Among the predisposing causes we find youth, most cases occurring between the ages of 15 and 25 years. It is rare in early childhood, and after fifty, although cases have been recorded occurring in children just a few months old.

In many cases the tendency to tonsillar inflammation seems to be distinctly hereditary. In such cases the inheritance might be due to the existence in parent and child of a common diathesis—the rheumatic, for instance. Climate may also play an important part. Hypertrophy of the tonsils greatly increases the liability of the person to attacks of tonsillitis. Often, this seems to be due to the retention in the large lacunae of excretory matter which acts as an irritant, and so excites the adjacent tissues that a tonsillitis supervenes. The tonsil seems in many cases, to be a vulnerable spot, which is apt to sympathize with various irregularities of the body, and to be subject to inflammation as the result of indigestion, menstrual irregularities, or uterine influence, the strumous diathesis, and most important of all, rheumatism and gout. Ill health is a predisposing cause, also mental depression and unusual anxiety or care.

The exciting causes are usually ascribed to be exposure to wet and cold; bad hygienic surroundings also favor the development of tonsillitis. Most cases occur in the spring, next most frequently in the winter, less in the fall, and least prevalent in the summer. The disease is uncommon in the tropical and in the very cold latitudes. Tonsillitis may be present as a complication in scarlet fever, measles, and smallpox. It may also be caused by the inhalation of irritating vapors, or the swallowing of caustic substances.

SYMPTOMS.

While the actual pathological conditions in tonsillitis may vary as between the several forms of the disease, there is clinically no well marked line of demarkation between the va-

ries described, and as regards treatment, it is sufficient to make two divisions; first, superficial or follicular tonsillitis; 2nd, deep or parenchymatous.

The symptoms which usher in an attack of tonsillitis are in general much the same for all varieties of the disease. In many cases of true suppurative tonsillitis, however, there is from the first, a sensation of deep-seated pain and the throbbing which, to the experienced sufferer, marks the attack as one of quinsy. The general symptoms are malaise, chilliness and febrile temperature, more or less pronounced, together with a sense of stiffness and dryness of the throat, and more or less pain in deglutition. As the soreness of the throat becomes worse, the temperature tends to rise until it may reach as high as 106 degrees. It is apt to rise to the highest point in the young, and in the follicular form of the disease may attain a maximum in a comparatively short time. Generally the constitutional symptoms are more marked in the suppurative form. In patients of a debilitated condition, the fever may assume almost a typhoid character while the tonsils become dotted with a grayish exudation, or are actually covered with sloughing ulcerations. In some instances the disease seems to be epidemic attacking several persons in the same household. The inflammatory process often extends to the mucous membrane lining the Eustachian tube causing a temporary loss of hearing and sometimes an inflammation of the middle ear. Dysphagia in a severe case of quinsy is often intense, the patient being unable to swallow even his own saliva and absolutely refusing to take food because of the inordinate pain caused by every attempt at deglutition and because from the tumefied state of the parts the stiffening of the muscles and the general local disability, the act of swallowing is a physical impossibility. The tongue is heavily coated and the breath very offensive and sordes are often on the teeth.

On inspection we see in acute follicular tonsillitis, the crypts of the tonsils are filled with a grayish material each one looks like a little pin head—often one tonsil is involved and then the other. The tonsils are swollen and engorged with blood and often block up the entire throat.

In parenchymatous tonsillitis we most often find that an abscess is forming and that one tonsil is inflamed and bulging. Sometimes the parenchyma of the tonsils inflame without abscessing and we have just enlarged tonsils without the crypts being filled up as in the follicular variety.

Paralysis of the pharynx and palate with or without anesthesia, occurs often after an attack of tonsillitis. Constipation almost invariably precedes and accompanies tonsillitis.

The urine is highly colored, loaded with urates, contains an excess of urea, and is deficient in chlorides. Albumin is sometimes found, rarely we find a rash in cases of tonsillitis.

PATHOLOGY.

Simple tonsillitis can hardly prove fatal unless complicated by some intercurrent affection so that few opportunities have been offered to study the effect of simple inflammation upon the gland. On inspection one or both tonsils will be seen to project from its bed as a rounded, deep red body, which may extend beyond the median line, when they may entirely occlude the isthmus of the fauces; the half arches and posterior border of the soft palate are reddened and swollen. The surface of the tonsils is often covered with small, yellowish points which closely resemble patches of false membrane, but careful inspection will show that they are beneath the mucous membrane, being only the distended follicles of the gland. The mucous membrane of the fauces and pharynx is also red and swollen.

DIFFERENTIAL DIAGNOSIS.

Of all cases that a general practitioner sees at this season of the year, the diagnosis at times of tonsillitis, seems to the writer to be the most difficult. First, tonsillitis may be mistaken for diphtheria. The points of difference that I think the most of, are first, whether or not there is an epidemic of diphtheria. If there is an epidemic it is best, I believe, to take no chances but give antitoxin freely.

2nd. Whether or not the patient has enlarged tonsils and is subject to attacks of tonsillitis. Some cases of tonsillitis have no temperature and a membrane that looks exactly like a diphtheritic membrane. These cases that I have observed have occurred mostly in people of 25 to 50 years of age, and as no other cases developed in the family, I took for granted that they were not diphtheritic. It would have been better if a microscopic examination had been made and in the future I intend to have several of these cases examined for the Klebs-Loeffler bacillus.

3rd. The temperature and pulse. In tonsillitis we have a temperature generally over 102 degrees F., and a pulse that is full, strong and rapid; while in diphtheria the temperature is usually below 102 degrees F., and the pulse is rapid, weak, and often irregular.

4th. General symptoms. In tonsillitis we have as a rule headache, headache, and pains in various parts of the body, although the patient feels strong, while in diphtheria we have a patient who is weak, but has not the headache, that we find in the tonsil case.

5th. Character of the Membrane. In the tonsil cases the rule is to have several punctate

spots that coalesce in a few hours, generally on one tonsil, but often on both. This membrane is strictly confined to the tonsils and is easily wiped off leaving a surface that does not bleed. In diphtheria the membrane is tough, does not confine itself to the tonsil and when wiped off leaves a raw bleeding surface. Tonsillitis may also be mistaken for scarlet fever, but the projective vomiting and the eruption will make the diagnosis clear. Syphilis is differentiated from tonsillitis by the symmetry of its manifestations and by the presence of ulceration the latter being unusual in tonsillitis.

Cancer, by the history, duration and it being unilateral.

DURATION.

The duration of an attack of simple parenchymatous tonsillitis is generally from three days to a week. If follicular tonsillitis it may run its course in from two to five days as a rule. In quinsy, the duration is uncertain, and there is a tendency to linger, and in many cases to relapse, sometimes lasting for several weeks.

PROGNOSIS.

The prognosis in the milder forms of tonsillitis is almost invariably good, and the progress toward recovery often very rapid. This is not always invariably the case. Sometimes follicular tonsillitis is followed by marked debility, or an attack of suppurative tonsillitis may succeed in persons of debilitated constitution, by a tedious convalescence. One attack seems to predispose to others, and with some patients every year brings one or more attacks.

Death from quinsy may occur in one of three ways: By sudden rupture of a large tonsillar abscess during sleep, resulting in suffocation; by the violence of the inflammation of the neighboring parts, which, extending to the larynx, produces oedema of the glottis; and by erosion of the walls of one of the large arteries adjacent to the tonsil, followed by fatal hemorrhage.

TREATMENT.

The first indication is for a prompt and efficient purgative and none is better than calomel and soda, followed in four or six hours by a saline. If the case is seen early the tincture of ammoniated guaiac may be prescribed in dram doses every two or three hours in the hope of aborting the attack. This drug has been highly recommended. Personally I like the salicylates in some form as they relieve the headache and the aches in general. I usually combine them with phenacetin and push these until the general symptoms are relieved or the ringing in the ears is produced. Locally any good cleansing gargle containing

some hydrogen-peroxide. Later if the tonsils are free from membrane but relaxed, an astringent gargle is indicated.

In parenchymatous (quinsy) tonsillitis if seen within the first twelve hours, cold can be applied in the form of an ice bag or ice cloths, if there is not improvement within the next twelve hours heat had better be used in the form of poultices to hasten the formation of pus. Most often the abscess will rupture after several hours of hot poulticing, but if it does not, and the pus can be located it should be evacuated by means of a sharp knife which has been wrapped with adhesive to within 1-4 of an inch of its point. This can be used to stab the tonsil in the places where the pus is suspected and even if you do not hit the pus you will relieve the tension and reduce the resistance so that the pus can be evacuated easier. After attacks of tonsillitis, and quinsy if the patient is debilitated, tonics are indicated.

In patients who are subject to attacks of tonsillitis that cannot be attributed to a diathesis, a tonsillectomy should be recommended. Often a physician is in doubt about his diagnosis and when he is in doubt and cannot have an examination made for the Klebs-Loeffler bacillus, I believe it is better to give antitoxin. Tonsillitis, I believe, is more contagious than we think, and it is well to isolate the patient, and especially if you cannot be positive of your diagnosis.

DISCUSSION.

Adolph O. Pfingst: The general practitioners probably know more about follicular tonsillitis than those who are doing special work, because they see more of it, hence I have been very much interested in what the essayist had to say.

I have been especially interested, in the past year or two, in the etiology of this condition. It seems to me that as we increase in knowledge of bacterial infections and specific remedies for certain infections, we will probably evolve some specific treatment of the various forms of tonsillitis. I think it is a conceded fact that ever since the various forms of staphylococci and streptococci were first recognized, and their relation to pus formation understood they are looked upon as the most frequently offending organisms in tonsillitis. In later years, as we have been recognizing more and more the importance of the colon bacillus as a pus producer, we are coming to believe that this also is a factor in the causation of tonsillitis. I do not think we should differentiate between tonsillar diphtheria and all other forms of tonsillitis as a group, for they all cause tonsil inflammation each case differing with the nature of the infecting organism.

I believe that eventually we will classify the various forms of angina according to the nature of its infecting element. In my judgment it is

in the streptococcal infection that we most frequently have complications, such as peritonsillar abscess or infected glands.

Personally I look upon the peritonsillar infections as secondary to an infection of the tonsillar crypts.

A few days ago I was called to see a graduate nurse, who was just getting over an attack of so-called follicular tonsillitis. I had seen and treated her only once during this attack. I found her suffering not only with difficulty in deglutition, but also of phonation and respiration; she was beginning to get hoarse and could hardly breathe. Within twelve hours after the beginning of these symptoms, she had developed a very large infected gland on one side, and when I saw her twelve hours later she had become cyanosed, and for a while it appeared that it would be necessary to do a tracheotomy. Dr. Allert had seen her in my absence, and later in the morning we both saw her again, at which time she had considerable oedema of the larynx most marked on the side of the enlarged gland. Unfortunately, no culture was made to determine the character of the infecting bacillus. Not knowing the nature of the infecting agent we gave her mixed staphylococcal vaccine, but it seemed to have little or no effect on the progress of the inflammation.

As to treatment, just one word which may be of interest to the general practitioners. I believe most of you use a compressed air apparatus of some kind. If these cases are seen early, I believe we can accomplish a great deal of good by cleansing the crypts of the tonsils. If we get them before the bacterial deposits have become so adherent that they cannot be removed, I believe that, by using the compressed air apparatus, cleansing the crypts, then get into them with a saturated solution of nitrate of silver, and at the same time begin the internal administration of aspirin, we can very frequently abort the disease.

Gaylord C. Hall: I have enjoyed the essay very much indeed. I have always had a peculiarly tender feeling for this subject, because I suffered with it for years until I had my tonsils removed.

I noticed that the essayist made a distinction between abscess within the gland and abscess around the gland, speaking of the former as "quinsy". My idea of quinsy is that it is rather of a peritonsillar type; that abscess within the gland is a very rare condition, which sometimes eventuates in complete necrosis of the tonsil. In a recent number of the *Journal of the A. M. A.*, I noticed an account of an epidemic of very severe tonsillitis, of the streptococcal type, growing out of an infection of the milk supply. I think this illustrates the point made by Dr. Pfingst, that all of these tonsillar infections differ only in severity, and where we have a virulent streptococcal infection of the tonsil, we have a very severe infection indeed. These infections may not only spread,

by means of continuity of tissue into the larynx, causing oedema there, but may also get into the general circulation, causing infectious endocarditis. Furthermore, it is not uncommon for severe cases of tonsillitis to develop a mild type of nephritis, usually clearing up soon. I have seen a number of cases with albumin in the urine. I have seen other cases with the well-known combination of rheumatism and tonsillitis. Only recently a child was brought to me for operation, but as she was not in good general condition at the time, operation was deferred. She developed tonsillitis from which she recovered in the usual time, three or four days after, but before anything could be done in the way of preparing her for operation, she was seized with acute articular rheumatism. I saw her again, six or eight weeks after she had recovered from the attack of rheumatism, and at that time she had a very loud mitral murmur. This case illustrates, I believe that there is a direct connection between infectious tonsillitis, infectious arthritis and the development of endocarditis.

The essayist spoke of tonsillitis occurring in elderly persons unaccompanied by fever. I would like to ask him if this condition is accompanied by a membrane, with an exudate? I would suggest the possibility of Vincent's angina, a rather unusual type of tonsillar infection, which very often spreads, eating out the entire tonsillar tissue. It may also involve the pillars of the fauces. This condition may be controlled by applications of iodine and the use of iodine internally.

While the doctor confines his remarks almost entirely to the acute types of infection, I believe that the most interesting field of study is offered by the chronic forms. It has been shown that from five to ten per cent. of these cases are tubercular. However, it is not possible to diagnose these cases clinically, as there are no classical signs in the throat. There is no doubt that these chronic cases of tonsillar infection are responsible for a great many obscure conditions. I have had five cases, three of which were diagnosed tuberculous where operation revealed a chronic abscess formation behind the tonsils. After operation these patients rapidly gained strength and the manifestations of tuberculous vanished. I think that, without doubt, many cases of recurrent arthritis in adults are due to absorption of infectious material within these glands.

In regard to treatment of the acute cases, I can endorse everything that Dr. Pfingst has said as to getting into the crypts. As to application to the membrane found either in the follicles or the diphtheritic form of tonsillitis, I prefer Loeffler's solution. You will find that, in children, it burns a little too much, but this can be overcome by diluting it with tr. benzoin comp., and it is far superior to nitrate of silver. After the infection has almost subsided, and you want to get

the vasomotor effect, then nitrate of silver solution is the very best thing to use on it.

W. T. Bruner: The essayist has covered the ground so thoroughly that he has left but little to be said. It seems that the tendency to-day is to diagnose all cases of follicular tonsillitis as diphtheritic, but I do not believe we are justified in doing so. Many of these cases can be treated successfully, with recovery in three or four days, without danger of infecting other children if the patient is isolated and kept away from school. That is where the trouble comes in; we should be better diagnosticians and able to differentiate between the various forms of tonsillitis. While, in the presence of an epidemic of diphtheria, it may be wise to classify all these cases under that head, still I do not believe that sporadic cases of follicular tonsillitis should all be called diphtheritic.

As to treatment, in acute tonsillar troubles, a two per cent. solution of guaiacol has proven more satisfactory than any other local application in my hands. With it I have very frequently succeeded in aborting these cases in a couple of days. Nitrate of silver is an old and good remedy, but it is not used in strong enough solution. I believe we should use a drachm to the ounce, and put it down into the crypts of the tonsils, which can be done with cotton on a cotton applicator. In cases where the patient has had repeated attacks of tonsillitis, of course the indication is to remove the tonsils after the patient has recovered from the acute inflammation. In most of these cases we should given anti-rheumatic treatment, because many of them have rheumatic manifestations.

F. Lee Cessna: I have recently had a little trouble along this line, and perhaps I might get some information. About six weeks ago I was called to attend a family of five persons, all suffering with what I diagnosed as tonsillitis. I gave them the usual treatment and they soon recovered with the exception of the youngest member of the family, a child of two years. This little fellow had considerable trouble. A membrane formed in the throat, he developed hoarseness, and after about ten days, ear trouble developed, both ears discharging pretty freely. It was a question in my mind whether this was a follicular tonsillitis, or whether it was diphtheritic. The child has since recovered. I did not use antitoxin.

Harry J. Phillips: I have enjoyed the paper very much, but I do not know that I can add anything to it. We general practitioners see a great deal of tonsillitis, especially at this time of the year, and the paper is, therefore, a very timely one.

John Karagiozian: It may be interesting to you to know what we do with these cases in my country. We do not use this drug and that drug, as you do, but we have some old women there who put their fingers on each side and press hard, and

if it is ripe it bursts, and that is an end of it. All of my family had this trouble, and whenever we had it we were sick a long time. Since coming to this country one of my children had trouble with his tonsils, and I took him to one specialist and he cut off a part of it, but he had it again and I took him to another specialist and he cut off some more, but still he had trouble, and I tried and tried and at last succeeded in getting rid of it. The last time I had tonsillitis in Syria, a physician there took his knife, and without sterilizing it or using any technic he just gave a punch and that was the end of it. Since then I have not had any trouble at all.

Wm. A. Keller: This paper is most excellently written and the essayist has covered the ground thoroughly. There are one or two little points that I wish to take notice of.

The essayist stated, I believe, that the ages in which tonsillitis is most prevalent are from 15 to 25 years. I think we find just as many cases under and over these ages.

Another point made by the essayist was in regard to quinsy. I think one of the most prominent symptoms of quinsy that we have is oedema of the uvula, which I did not hear the doctor mention. I do not remember of seeing a case of quinsy that did not have oedema of the uvula.

In regard to differential diagnosis, a very important point is the eruption. We frequently find in tonsillitis an eruption that on the first day simulates very much the eruption of scarlet fever. The difference is that in scarlet fever the eruption is a red rash, while in tonsillitis it presents a dotted appearance. I have noticed that in these cases the trouble is usually due to some error in diet, giving rise to an auto-intoxication, or, in those of a rheumatic diathesis, from exposure to cold.

As to aborting these attacks, I have noticed that very frequently, especially in children, they begin with high fever, aching all over, etc., and they do not complain of much pain in the throat during the first twenty-four hours. Calomel followed by a saline purge, salicylates and phenacetin will get rid of a good deal of this aching, and the next day the child will have a very sore throat. I doubt very much, and always have, whether we are able to abort an attack of follicular tonsillitis by blowing out the crypts and making applications, but I have observed that two or three applications of a very strong solution of nitrate of silver, 60 to 90 grains to the ounce, will greatly relieve the pain in the tonsils.

I agree with Dr. Pfingst in regard to tonsillar abscess; that this condition is very rare, but we frequently see peri-tonsillar abscess as a sequela of tonsillitis. Of course, we should put on hot applications, etc., but when we have oedema of the glottis, I think it is a good idea, instead of wrapping your knife to within a quarter of an inch of the point, to leave half an inch bare and

make a pretty good incision. Of course, you must be careful and know your anatomy so that you will not cut the arteries lying behind, but make a free incision and you will find that it gives relief. I know of no condition in surgery where the knife gives as much relief as in peri-tonsillar abscess. In nine cases out of ten you can make diagnosis without looking at the throat, by the peculiar voice. The abscess is generally pointed and the thing to do is to make incision first and apply hot poultices etc., afterwards.

In regard to Dr. Cessna's case, he stated that there was a membrane on the child's throat. I am inclined to think that the doctor probably had diphtheria to contend with, because I do not know that we ever see a membrane in follicular tonsillitis, although we frequently have an exudate from the crypts of the tonsils that sometimes looks very much like a membrane, but in such cases the healthy tissue can be seen between the spots of exudate which is not the case in diphtheria. He will find out later on whether this was a diphtheria or not, and I would suggest that he watch the case rather closely, because the child is apt to develop paralysis of the fauces, evidenced by the fact that when water is taken it will come out through the nose. I have frequently treated children, who, following an attack of so-called tonsillitis, could not swallow very well, and talked somewhat peculiar. Another thing that makes me think this was a case of diphtheria is the fact that the child developed hoarseness. We seldom, if ever, find hoarseness in tonsillitis, because as a rule it does not affect the vocal cords.

Wm. A. Jenkins: I wish to briefly mention just three points, two with respect to diagnosis and one in regard to treatment.

First, I would say that whenever we see a child or a young adult, with aching pains—headache, backache, loss of appetite, etc., we should never prescribe for it as a case of gripe without looking at the throat. We should always, in doubtful cases, carefully investigate the throat.

The next point in connection with diagnosis is this: The first time we see a case of sore throat we should be satisfied with saying to the family, or to the patient, that there exists an inflammatory condition of the tonsils, and we will have to watch it and await results, because oftentimes the tonsils is the portal of entry of the acute infectious diseases. Take the acute exanthematous diseases for instance. Many times they begin in the throat, and the patient will have a sore and enlarged throat for several days before there are any other manifestations of the trouble. I have seen cases of scarlet fever in which the patient had a tonsillitis for at least a week before the eruption appeared. Any number of textbooks have called attention to this fact.

Just one point about treatment. I think, at the present, both the specialist and the general practitioner understands pretty well that the

proper course is a combination of both systemic and local treatment. There was a time when it was considered that the treatment was all local, and but little attention was paid to systemic measures. I remember an epidemic of tonsillitis that occurred when I was a medical student, and the specialists undertook the treatment of these students, having them come every day, blowing out the crypts and putting various antiseptics on the tonsils. Had these boys had the systemic treatment mentioned by the essayist, they would not have had nearly the amount of trouble they did have in getting rid of the tonsillar condition.

For the local treatment, perhaps nitrate of silver is as good as any. A great deal of the infectious material can be swabbed off the tonsil; then take a drachm-to-the-ounce solution of nitrate of silver and apply it thoroughly to the infected portions. Another exceedingly good application is Monsell's solution, 50 per cent. In treating nearly a hundred cases of tonsillitis among the children in institutional work, I gave them broken doses of calomel, followed by saline, one of the salicylates, and the above-mentioned local treatment with excellent results.

F. J. Keifer: I wish to thank the essayist for his very excellent paper. It has been so thoroughly discussed that there is hardly anything to be added to it. One point upon which I lay a good deal of stress should be in connection with the teeth. I believe that a great many systemic infections causing tonsillitis are caused by defective teeth.

In my practice I like a mixture of peroxide of hydrogen and bichloride of mercury for a local application in cases of acute tonsillitis.

Virgil E. Simpson: I believe I have suffered from tonsillitis in every form in which it is possible for the disease to manifest itself.

I would like to emphasize the necessity for microscopic examinations in all cases of tonsillar involvement. In this way we eliminate the possibility of overlooking a diphtheria. If diphtheria is present, specific treatment is indicated, and if diphtheria is not present, it is equally important in my judgment, to determine just what character of infection we have to deal with.

So far as the treatment of tonsillitis is concerned, I have lost confidence in practically everything that has been recommended in the way of drugs. I have used every form of local treatment, both on myself and those under my care, and I see little difference in the results obtained from one form of treatment as compared with another. I have used Loeffler's solution, Monsell's solution, nitrate of silver, protargol, argyrol, and what-not, and I do not believe any of them do a great deal of good. Tonsillitis is not a surface involvement; the mere application of a solution locally on the tonsil does not get rid of the infection. It is true, however, that nitrate of silver does relieve the pain, to a certain extent, just as the coal-tar preparations, codein, salicylates, etc., given in-

ternally will promote comfort and make the patient feel better, but, so far as modification of the course of the disease is concerned, my personal experience has led me to conclude that no treatment among those which I have tried, either internal medication or local applications, has been satisfactory.

To go back to the necessity for making microscopic examinations, I wish to say, in this connection, that the treatment *par excellence*, in my judgment, is the administration of vaccine. In practically every case of tonsillitis that I have seen in the past two years, I have made it a routine practice to examine the exudate microscopically, and I have found pretty nearly every possible organism present in the tonsils at one time or another. In the last case I saw, there were two strains of staphylococci, streptococci and colon bacilli present. I used mixed vaccine in this case, trying to get at the root of the trouble by combining the strains.

I have seen as much oedema from acute follicular tonsillitis as I have ever seen from diphtheria, as far as the soft palate is concerned. I have seen unquestionable membrane on the tonsils in cases which were not diphtheritic, as proven by more than one microscopic examination. The character of the exudate in these tonsillar conditions differs very materially from the diphtheritic exudate. The latter is of a peculiar color, resembling the ash of a cigar, and is thick and fibrinous, whereas the exudate observed in the more virulent forms of tonsillitis is much lighter in color.

I wish I knew of something that would prevent tonsillitis; I am more interested in the prophylaxis than the cure. I have tried immunizing with vaccines, and last year I thought I had been successful, as I went along without an attack until the middle of April, when I suffered one of the most virulent attacks I have ever had.

C. L. Nichols, (closing): I wish to thank the gentlemen for their discussion of the paper.

In regard to tonsillar abscess, it seems that most of the text-books classify anything like an abscess connected with the tonsil as a quinsy. Most cases of quinsy are, I believe, originally tonsillitis, but occasionally we see a case where there has been no tonsillar involvement at all, and yet an abscess has formed back of the tonsil. Of course, it is possible that this infection might travel through the crypts and not be noticed.

I selected this subject for my paper because of the trouble we have, especially at this time of the year, in differentiating between the diphtheritic and non-diphtheritic cases.

MULTIPLE RUPTURE OF THE SMALL INTESTINE

By ALBRO L. PARSONS, Louisville.

Multiple subcutaneous rupture of the small intestine is comparatively rare, only nine out of Gage's eighty-five cases having sustained more than one laceration. Therefore, the following case, which I report through the courtesy of Dr. Dugan, may not prove without interest.

C. R., male; colored; 45 years old; fell about 40 feet from a scaffold. The details of the fall are unknown. I saw him shortly afterwards at the City Hospital, 4:00 p. m., November 7th, 1911. He was in profound shock. Examination revealed, a small scalp wound over the sagittal suture, one inch long, but no fracture. The left eye was contused. The floor of the left axilla was torn open from the anterior to the posterior folds, the muscles being uninvolved. It appeared as if he had grabbed some support while falling, and the weight of his body had been almost sufficient to tear the arm loose. The left shoulder was dislocated, the humeral head resting under the middle of the clavicle. Chest normal. The abdomen was flat and slightly tender, but at no particular point; there was no abdominal pain. The recti were all but relaxed. A small umbilical hernia of long standing was noted with the sac empty. Urine bloodless. The patient complained bitterly of his shoulder, and was given morphine, gr. 1-4, atropin gr. 1-150, both for this pain and as a preliminary to the anesthetic. Under the application of heat, etc., he rallied promptly from the shock, and was then anesthetized. The shoulder was reduced, the axilla packed, and the patient returned to bed in good shape.

November 8th. Condition good; patient comfortable. Abdominal conditions were similar to those found on the preceding day. At 5:00 p. m., he complained, for the first time, of abdominal pain. Tenderness and rigidity were the same (very slight), but the abdomen was somewhat distended. His bowels had not moved. I noticed, for the first time, the absence of peristalsis, and expressed the belief that we were dealing with an adynamic ileus following shock. Orders were left for enemas to be given, and that results be telephoned me later. At 11:00 p. m. Dr. Bailey kindly notified me, that the enemas had returned clear; and no gas had passed. The patient was again in shock; pulse 160; temperature 101; expression anxious; abdomen ballooned; great abdominal pain; muscles tense and general tenderness all over abdomen. He had not vomited.

As soon as possible the abdomen was opened in the mid-line. The cavity contained a little

foul-smelling, pea-soup-like fluid; no free gas was detected, nor could I identify any feces. All the peritoneal surfaces below the transverse meso-colon were inflamed and coated with pale butter-like lymph, which in places reached a remarkable thickness. This also filled the little hernial sac. At about the junction of the ileum and the jejunum a rupture was found. It was opposite the mesentery, and large enough to admit the finger-tip. The everted mucous membrane so effectually plugged it that little or no gas had escaped from the enormously distended coils in the vicinity. Closed by Lembert suture. Reading downward about four feet above the ileo-cecal valve, a rent one inch long was disclosed. The edges were ragged and the wound gaped open. The gut in the neighborhood was collapsed. Rupture closed. Reading upward from the first tear, and about four feet therefrom, I came upon a third rupture—a duplicate of the first. Patient's condition was now very bad; pulse 180. Anesthesia stopped and 1,000 c.c. of saline solution given. As no blood was found in the cavity, I argued that the liver, spleen, etc., had escaped harm. The fluid in the abdomen was rapidly absorbed with wet sponges, and the wound closed with through and through silk-worm gut, after inserting a tube down into the pelvis. Having washed the stomach out, the patient was returned to bed and the Murphy treatment for peritonitis instituted.

The next day, November 9th, the patient was fairly comfortable; pulse 150; no gas was passed. He vomited at times, and during the day the stomach was washed at intervals.

November 10th, condition practically the same until 11:00 p. m., when he died. Dr. Leon K. Baldauf kindly did a post-mortem. He reported that, other than the three ruptures, there was no visceral lesion. The repaired intestinal rents were properly sealed.

We have here illustrated two types of rupture. That nearest the valve was undoubtedly the result of direct force. The location of the rupture, its shape and its ragged edges, all point to the gut having been caught between the traumatizing agent and the sharp saccal promontory (Andrews). The two other lesions were of the "blow-out" variety. They must have occurred in loops, the ends of which were occluded by kinks, by the force, or both (Sauerbruch), and in which the intraluminal pressure had been raised to the bursting-point. As in nearly all such ruptures they were situated on the free border. I do not believe that this case meets Bunge's suggestion of rupture occurring in herniated intestine, which later withdraws from the sac. Although the patient had an umbilical hernia, it was far too small to accommodate three coils,

even if they were situated close to the ring, which was not true in this case.

The diagnosis of visceral injury demanding surgical intervention, is not difficult even in early cases when based on such classical symptoms as history, pain, shock, vomiting, abdominal rigidity, etc. There is, however, no pathognomonic sign of intestinal rupture occurring with sufficient regularity to enable the surgeon to conclude anything more definite than that he is dealing with grave peritoneal insult. However, it is to the atypical cases that I wish to call attention, for their symptoms are so irregular, both in regard to intensity and time of appearance, as to render timely diagnosis extremely difficult.

Theoretically, but not always practically, the symptoms should be divided into the pre-peritonitis signs and those due to inflammation of that membrane. He will obtain the best surgical results who can earliest recognize and properly interpret the former. It is most unfortunate that in many cases the first symptoms which draw the attention to the abdomen are those of commencing peritonitis. Pre-peritonitis signs are at times entirely lacking until so late that their appearance is simultaneous with the peritonitis. Curtis, Senn, Means, Battle, Bryant, Robson, and others, all speak of *delayed* symptoms. Stone had this in mind when he wrote, "The symptoms of peritonitis may be delayed, appearing some time after shock has subsided, and following an interval of marked seeming improvement." Quoting Robson: "The usual symptoms might be absent for a time, only becoming evident after some hours, and failure to diagnose might occur from injuries to other regions taking the attention away from the abdomen." This, I believe, is what happened in my case. The patient entered the hospital with his intestine ruptured, but the symptoms were not only delayed, but masked by his other injuries.

Mr. Bennett, in discussing Robson's paper, declares that a week is not too long to regard abdominal contusions with suspicion, and relates of a boy struck by a cricket ball, whose only symptom was tenderness. A week in bed restored him apparently to health, but when allowed to arise, he fainted and died. An autopsy showed a complete rupture of the duodenum.

Mr. Bryant reports two such instances. The first did well until the 19th day, when he died and at autopsy a perforated duodenum was found. Could this have been an ulcer? The other, he describes as "perforating on the fifth day." Autopsy revealed a laceration four inches above the cecum. The present state of our knowledge allows us only to advance surmises which may explain this tardiness in certain cases; for instance, in blow-

outs, the mucous membrane plugs the opening, preventing the escape of intestinal contents (Stone). This barrier may at any time give way. The two blow-outs I observed were effectively closed. Again, if the intestine is only contused, it may be days before the weak spot breaks down. Jobert (Keen) and Senn call attention to incomplete ruptures, which involve one or two coats of the intestine only. Poland mentions two such, one affecting the mucous membrane, and the other the serosa. These cases may later become complete ruptures. They, however, partake more of the nature of a perforation similar to that occurring in typhoid fever, and should not properly be considered ruptures. A retro-peritoneal tear, as might occur in the duodenum, will also explain some cases of delay.

One of the most misleading symptoms may be the history. If the rupture occurs by indirect force, the anterior abdominal wall will not have been struck at all. Senn's patient, while walking, slipped and fell upon the buttocks. Bottomly and Westbrook each report similar cases, their patients having been struck from behind. The patient's actions after the trauma may be not at all in keeping with so grave a lesion. Out of 100 abdominal contusions, collected by Michaux, 10 continued their vocations for a time; some even with complete laceration of the intestine (Senn). Rioblane reports two such cases. Poland treated a child of thirteen who walked a mile with a lacerated duodenum. Battle saw a man who finished his work (an hour and a half) and even returned to it the next day, after a kick which resulted in a rupture. Gage's case was very similar. Professor Enderlen's patient, with multiple ruptures, walked home and did not go to bed for hours, and Bryant's case No. 21, came to the hospital on foot.

The trauma itself may be deemed insufficient to cause so much damage, yet no greater mistake could be made. A fall from the erect to the sitting posture was sufficient in Senn's case. Bryant saw a child who, at play, fell on the sidewalk and ruptured the ileum. Many of the above-mentioned cases, even when caused by direct force, showed no signs of injury upon the abdominal wall. My case, after a fall of forty feet, presented no such evidence except the slight tenderness already noted.

Pain, Nature's so-called red flag, may fail us as a symptom. It was slight in 29, and totally absent in 6 of Sherck's 182 cases of visceral injury. Makin says it may subside to reappear later, in one case as late as the third day. In his series of 21 cases, only two are described as having severe pain. A patient observed by Chavasse had severe pain at first (3:00 p. m.); then felt comfortable until the

next night, when he vomited and died of rupture of the jejunum (Senn). Jolley's case had no pain for 38 hours; Golden's for 10 hours. Royster states that his patient, a boy of eight, had no pain at all, and Buchanan reports a similar experience. The patient observed by Battle, though run over in the afternoon, did not suffer until nine the next morning. This was true of Knagg's patient, who fell at 2:30 p. m., and did not complain until the following day. Parkinson's patient did not mention her abdomen, after a fall, but complained bitterly of her ankle, yet died of ruptured intestine. However, in 97 per cent. of visceral injuries, pain will be a feature (Sherck). In my own case it was 26 hours before the patient complained of abdominal pain, which was after peritonitis had set up.

Tenderness is an important symptom. It is allied to pain and nearly always present. In Makin's series it was mentioned 16 times, and of these two failed to exhibit it. Perez (Keen) lays stress upon the tenderness becoming general, and not confining itself to the site of injury. General tenderness, I take it, is a symptom of peritonitis and, therefore, appears too late for the attainment of best results. As a symptom, tenderness gains in importance if it occurs in a case where the abdominal wall has escaped injury; that is, in ruptures by indirect force. As above noted, the case reported to-night had slight tenderness, which was mistaken for jail injury. On the other hand, case No. 4, cited by Stone, had slight though general tenderness. An operation revealed, not rupture, but a large contusion of the ileum.

Closely allied to pain and tenderness is muscular rigidity—an almost unailing symptom of visceral injury. That it may fail, however, is shown by an analysis of 159 such cases in 20 of which it was slight, 7 appeared late, and in 7 not at all (Sherck). It is well known that the muscles, at first rigid, may relax (Campbell, Enderlen, etc.), but this is probably due to ensuing peritonitis. Out of Makin's series, it developed early in 13, but in 4 it did not appear until late—7 to 18 hours. Thomen makes the amazing statement that it appeared in less than one-third of his series, 6 out of 20 (Eisendrath). This is directly at variance with Hartman's observation of 17 ruptures, in all of which rigidity played a role, while in 20 abdominal contusions, without rupture, it was not present (Senn). In visceral lesions in general, rigidity may be demonstrated in 90 per cent. (Sherck).

Shock is the one symptom we would most confidently expect. However, Sherck places it third among the symptoms of visceral injury—82 per cent. It was totally absent in 17 out of 94 of his series, while in 31 it was mild. None of the patients above mentioned, who

continued their vocations, could have suffered much from shock, certainly not early. Bryant's cases, Nos. 13 and 25, were not shocked at all, and case 20 very little so. None appeared in 3 out of 18 of Makin's series where mention was made of it. Jolley, Buchanan, and others, report similar observations. My patient was in profound shock but his many other injuries seemed sufficient cause.

Buchanan's case, which had neither pain nor shock, did vomit, a most valuable symptom. My case did not do so until after the second operation, when peritonitis was well advanced. Trendelenberg and Berndt consider vomiting almost pathognomonic. (Senn, Eisendrath). The latter goes so far as to believe that vomiting is only slight if the bowel is contused, but if torn, the nerves are exposed to the irritation of the intestinal contents, and the vomiting is severe. Emesis, however, will follow blows over the solar plexus, and may accompany shock from any cause. It did not occur in Bryant's case No. 25, nor in Golden's patient. Knaggs and Campbell, both speak of its being delayed. On the other hand, Holland reports a child who, upon falling downstairs, vomited, and presented no other symptoms until she died 24 hours later of ruptured jejunum (Senn).

Sherk's essay should be considered classic if for no other reason than the emphasis he lays upon the absence of peristalsis. Gaub demonstrated that abdominal trauma, followed by paresis of the gut, which does not subside in a few (four) hours, is almost certain evidence of serious injury. This is equally true when paresis recurs, or reappears after reaction has taken place (Sherk). He reports cases whose only symptoms were vomiting and paresis, and who were found to have sustained rupture. Conversely, where all signs pointed to rupture except the absence of peristalsis, operation revealed no lesion. Claybrook and others have noted this point. Buchanan, in the face of the fact that his patient had no shock, no external injury, and so little pain that morphin was not required, made a diagnosis of rupture from slight vomiting and paresis. He found a small rupture. Adynamic ileus must, of course, be kept in mind, but such cases usually clear up in four hours or less. However, Stone operated upon a case with complete paresis and found only a contused intestinal wall. The patient recovered but the bowel remained paralyzed for ten days. My patient had paresis, which, in conjunction with the vagueness of the other abdominal symptoms, I mistook for adynamic ileus. On the whole, I am inclined to regard paresis as a most trustworthy symptom, and am surprised at the frequency of its mention by observers—only five times out of 265 collected cases of abdominal contusions. In two

of these it was absent and no lesion was found (Sherk).

The facies abdominalis deserves mention. It usually appears early, but may not be marked until the advent of peritonitis. My patient may have presented it, but it was noted by none who observed him. After peritonitis was established it was, of course, very plain.

Among the minor symptoms the following may be noted as important in the chain of evidence, but their absence must not be too significantly regarded. Bloody stools rarely occur. The hemorrhage is not profuse as a rule. It may occur into the cavity, not into the gut and, furthermore, the paralyzed intestine fails to pass it on to the rectum. Enema, as in my case, often do not reveal its presence. With such peritoneal trauma we would expect the patient to lie with knees flexed even before peritonitis, but the patient I saw lay straight out in bed at all times. Abdominal distension comes on late, and should be considered a sign of peritonitis. Rapid superficial respiration, mentioned by Perez (Keen) is certainly allied to muscular spasm, and becomes more marked with the advancement of peritoneal inflammation. Both these symptoms appeared late in my case. The diminution of liver dullness is most important, as it shows free gas in the cavity, but is by no means constant and was not present in the case I report. Leucocytosis, and the demonstration of fluid in the flanks, are valuable but not sufficiently so to be waited for. The temperature is of little help. The pulse is invariably accelerated, no matter how illy-defined the other symptoms of rupture may be.

With so much that is indefinite, in the symptomatology, it is not surprising that mistakes in the interpretation of symptoms have been made in both directions. Koerte says he has made positive diagnoses from clinical symptoms, yet in spite of the fact that the patients were not operated upon, they have recovered. (Enderlen). Monroe has opened useless cases and says he will probably do so again. Many, however, have erred on the other side, and the delay has proven fatal. Bottomly analyzed an equal number of cases of abdominal contusions with and without visceral injury, and found that shock, pain and vomiting "varied in individuals in the early hours, irrespective of the nature of the lesion, and many cases could only be decided by exploration." (Stone). As surgeons we know that, where a reasonable doubt exists, it is safest to explore, yet it must be acknowledged that it is hard to make the patient assume this viewpoint. Under such conditions it is probably best to throw the responsibility upon the patient and his friends after a full and frank explanation.

The treatment is entirely surgical. The location of the incision has been a matter of controversy, some advocating the mid-line, others advising the site of injury. My own preference is the former. Most injuries occur below the umbilicus, on account of the thinness of the walls of the ileum and the role played by the sacral promontory. If other lesions are disclosed, this incision is equidistant from either flank and can be readily extended upward. Although speed is much to be desired, it is hard to attain. The appearance of the peritoneum leads one readily to the rupture, unless the contents of the bowel have been dispelled over the entire cavity by an explosive-like action. Then everything is matted together and the intestine must be read from one end to the other. Had I not done this I might readily have overlooked at least one rupture. All this must be done as gently and with as little handling as possible. Ruptures the size of those I found are closed by Lembert suture, but at times resection is necessary. In some cases, if the rupture is low down, and the condition of the patient demands desperate measures, a temporary fistula may be made. Tears in the mesentery and other lesions having been corrected, the treatment becomes that of peritonitis, which is beyond the scope of this paper.

DISCUSSION.

W. C. Dugan: I saw this patient with Dr. Parsons, and I do not think he need feel that there

you are very skilled in physical diagnosis, you will, upon percussion, be likely to mistake a distended colon, with gas separating the liver from the abdominal wall, for a rupture of the intestine. Again, we may have adhesions about the liver giving rise to the same condition, so that free gas in the cavity has very little, if any, value as a diagnostic sign of rupture of the intestine. If we see the patient early, when there is leakage into the abdominal cavity with no adhesions in the liver, then it is a very valuable sign indeed. Later on, when general tympany has become pronounced, I doubt the ability of even a skilled diagnostician to make a diagnosis by outlining the area of hepatic dullness.

What I consider the most valuable symptom of rupture of the intestine is delayed shock, which is usually found in rupture of the intestine with leakage of gas or fluid, coming on some time after the patient has reacted from the first shock. That is what is called secondary shock. Then we have shock coming on later, as mentioned by the essayist, upon separation of the adhesions of the coils of intestines overlaying the rupture. What has most likely occurred is that hemorrhage has taken place in the wall of the gut which has become septic or congested, and we have the secondary condition Dr. Parsons speaks of.

The treatment of these cases is purely surgical and, as the essayist has stated, the earlier diagnosis is made, the more favorable the outlook. If we see the patient before twenty-four hours have elapsed and make diagnosis of rupture of the intestine, the prognosis is reasonably good. When the patient has a very rapid pulse, with the peculiar appearance of the face indicating sepsis, and a great amount of distension, I do not think we can expect very much from operation. I believe the best thing to do in such cases is to treat the patient just as we would treat a case of fulminating appendicitis, simply making a stab wound and introducing a drainage tube. I doubt whether extensive surgery is indicated, as most of these cases will die on the table, or within a few hours after operation, and I believe a larger proportion of them will get well under the more simple treatment, trusting to nature to take care of the infection.

C. B. Spalding: I have thoroughly enjoyed Dr. Parsons' very excellent paper, particularly because I had a similar experience in a case of this character.

As Dr. Dugan has stated, two conflicting things that make for a bad prognosis are, first the fact that a good result depends upon an early diagnosis, whereas early diagnosis is made difficult by the late symptoms. One symptom that occurs probably as often as any other, is rigidity of the muscles, sometimes appearing even before there are any symptoms of shock. In this type of cases the diagnosis is often confused by the history, which was true in Dr. Parsons' case. I think this should teach us that, in the presence

was any lack of diagnostic skill on his part in having failed to detect the condition that was present, in view of the fact that it was so greatly masked by the other and more apparent pathology. When I first saw this man his arm was thrown out in such a position that it looked as if the end of the bone had penetrated the pleural cavity. He also had an injury to the head.

The diagnosis of internal rupture is often very difficult. The injury may have been slight, just a blow upon the abdomen, and the patient may lapse into profound shock, or a swoon, and remain in that condition for some time. Again, as stated by Dr. Parsons, an individual may have an extensive rupture and go along for quite a while before there are any manifestations suggestive of rupture of the abdominal viscera. Hemorrhage is nearly always slow in these cases, unless the kidney, liver, or other solid organ is involved. If the spleen is injured, we will have clotting around that organ as suggested by the essayist.

The subject of injury to the intestines was first called attention to by Flynn, many years ago, and it was thought that the question of penetrating wounds of the hollow viscera had been about settled. However, so many of the symptoms that we expect to find in rupture of the intestine are also present in other conditions, that they are very misleading. For instance, unless of a history of any trauma to the abdomen, we should be on the safe side and make early diagnosis by exploratory incision if necessary. This will do the patient no harm and may save his life.

I have had, in my own experience, a case similar to that related by Dr. Parsons, but until tonight it had not occurred to me that the trouble was in all probability rupture of the intestine. I was called at night to see this man who gave a history of having received a blow in the abdomen. He was not suffering very much pain, and I told him I would see him the next day. When I saw him again he had a general peritonitis. I advised prompt drainage, but by the time he had made up his mind to undergo operation his condition was such that I declined to operate. He died, and post-mortem examination showed a wound, which looked almost exactly like it had been made by a gunshot, in the small gut adjacent to the left inguinal canal, with the mucous membrane everted. The man gave a history of having had a hernia, and I do not know whether he had a rupture, or whether a sloughing piece of the gut slipped back into the cavity at the time of the injury.

I think the chief lesson to be learned from this very instructive paper is that when we get a history of injury to the abdomen we should lose no time in opening it, explaining to the patient the great danger from a possible rupture of the intestine, and the comparatively slight, if any, danger from an exploratory operation.

Guy P. Grigsby: I have seen one case in my own practice similar to that reported by Dr. Par-

sons. This was a man that I saw in consultation with Dr. Farmer. He gave a history that, while in an intoxicated condition, he had been thrown from an automobile, striking his hip against a rock wall. He was attended by several doctors at the time of the accident, morphine being administered, and he was also given several additional drinks by his friends. I did not see him until 10 or 11 hours after the accident, at which time Dr. Farmer and myself went over his abdomen very carefully, but were unable to elicit any thing that would indicate that this man had incurred any injury to the abdominal viscera. We did, however, find that he had a fracture of the neck of the left femur, and he was made comfortable for the night with sand-bags. We saw him again the next morning, at which time his pulse had dropped and his general condition appeared to be good. We again went over his abdomen, but there was still no rigidity, point of tenderness, nor anything suggestive of injury to the abdominal viscera. Therefore, we did not deem it necessary to wait any longer, but gave him an anesthetic and put him in a plaster spica. He went through that day and night very comfortably without the use of an opiate of any sort. When I saw him the next morning he was uncomfortable, which I thought was due to the plaster. His general condition was apparently good; pulse about 100, and I did not anticipate any trouble. I was called back to the hospital about two o'clock that afternoon, because of the intense pain which the patient was suffering, and as soon as I walked into the room I noticed that he had the facial expression typical of general peritonitis. I called Dr. Farmer and we cut the plaster. We at once noted that there was beginning distension and realized that we had a more serious condition to deal with than we had anticipated. Dr. Vance saw the case an hour or two later. After removal of plaster the patient was extremely restless and evidently started a hemorrhage, and the man went rapidly into shock and died that night. Unfortunately, we were unable to get an autopsy, but we came to the conclusion that the man had an intestinal rupture, probably of the sigmoid.

It seems to me that it is very hard to determine just what we are dealing with in these cases. Of course, in cases where a large vessel is ruptured with the pronounced symptoms of internal hemorrhage, the diagnosis is comparatively easy. Also in those cases where the intestines are distended and, as soon as rupture occurs, there is extravasation of the contents, with the consequent profound impression upon the peritoneum, together with the characteristic rigidity and tenderness, the diagnosis is not difficult. But, in those cases where the intestinal opening is small, or the intestinal contents are more or less solid in character and leak out very slowly; where the symptoms are slow in manifesting themselves, and there is no muscular rigidity, nor anything

upon which we can base a diagnosis, it is exceedingly difficult to arrive at a definite conclusion. In such cases it would appear that, if the patient's consent can be obtained, exploratory operation is the thing to do, and will unquestionably clear up all doubt in the matter; but it has been my experience, in one or two of these cases that I have seen in hospital work, that it is a very difficult matter to get the patient's consent to do an exploratory operation unless there is a great deal of pain, and, as a rule, consent is not given until it is too late for operative interference to do any good.

Chas. Farmer: I agree with the previous speaker that diagnosis of ruptured intestine is very difficult; usually there are other serious injuries complicating it. In the case Dr. Grigsby referred to, I saw this patient shortly after the injuries were received. The man was intoxicated and was a very nervous individual, which made the diagnosis in that case more difficult. When I saw him I gave him a dose of morphine and left him. About two or three o'clock I received a telephone message that he was suffering a great deal of pain. I at once sent him to the infirmary and on the way there he evidenced a great deal of thirst, calling for a glass of ice-water every square or two. The next morning, however, after having rested at the Infirmary all night, he seemed to be much improved. As Dr. Grigsby stated, he had a fracture of the femur, which was put up in a plaster cast, and he seemed to be doing very well until Tuesday morning, when he developed distension and died about sixty hours after receipt of the injury.

S. C. Frankel: I saw the case Dr. Parsons cited. I did not examine the patient at that time, but took only a superficial look at him. He was just coming out of shock, and I did not examine his abdomen and had no idea that he had any injury there. I thought the profound shock was due to the injuries to his head and chest. Upon hearing several days later that this patient had died of rupture of the intestine, I was very greatly surprised.

Irvin Abell: Dr. Parsons has presented the subject in a very interesting and practical manner.

Rupture of the intestine due to direct violence is much easier to diagnose and treat than those due to indirect violence. My own personal experience has been limited to those due to direct violence, and, strange as it may seem, all of these cases, five in number, have been due to the wheels of some vehicle passing over the abdomen. Two of them accepted the suggestion that the abdomen be opened. In one the intestine was found to be torn in one place, and in the other, while the intestine was not torn there were multiple haematomata in the intestine and mesentery.

Of the other three, two presented profound shock and one presented haematuria. One was

advised to have his abdomen opened, refused, and died; the others were simply kept under observation and recovered.

It seems to me that, in cases where there is a history of direct violence to the abdomen, the only sure way to determine the extent of the injury is to open the abdomen, and this should be done at a time when operative interference offers the greatest chance of success. In cases of the type reported by Dr. Parsons, where the injury is indirect, or where there are associated lesions of such gravity as to account for all the symptoms manifested, it is a matter of impossibility to make diagnosis until such local signs appear as direct the attention to the abdomen, and when these do appear it usually means the onset of peritonitis, which, unfortunately cannot always be controlled.

Bernard J. O'Connor: One feature of these cases to which I wish to call particular attention is the pulse rate. I believe that, in traumatic rupture of the intestine we have an analogy to disease conditions such as appendicitis, etc. Moyuahan has laid great stress upon the fact that for three or four hours there is little or no increase in the pulse rate; that it does not as a rule, increase in rapidity until there has been a certain amount of toxic absorption. The case Dr. Grigsby detailed is illustrative of this point. I have recently seen several cases of appendicitis with perforation where the pulse rate was not over 72.

I believe that, in some cases of abdominal trauma, rigidity and other symptoms are entirely absent. I saw one case of this character last summer in a man who had fallen from the fourth story of a building and sustained a broken ankle. His pulse rate was 90, general condition good, and he manifested very little evidence of shock. The ankle was put up in plaster of Paris, and 36 hours later the patient showed evidence of shock, which was so intense as to carry him off within four hours after the first symptoms. At no time had he shown any manifestations of injury to the abdominal viscera, except that blood was found in urine obtained by catheterization, but this all cleared up and the amount of urine eliminated was normal. A small amount of blood was also found in the first bowel movement following an enemata, but the second specimen showed no trace of blood. What brought on shock in this case I was unable to learn, as autopsy was refused, but my opinion was that it was due to an intestinal perforation and peritonitis.

A. David Willmoth: There is just one point that I would like to mention in connection with this valuable essay; that is, the question of rigidity which has been referred to by previous speakers. It is perfectly clear why we do not have rigidity in some cases, and why we do have it in cases like that mentioned by Dr. Grigsby. For instance, in conditions such as per-

forated gall-bladder in typhoid fever, or perforated appendicitis, where we have a pouring out of gas or infectious material from the gut, the muscles of that area become paralyzed to such an extent that rigidity does not take place. The same thing may be produced by traumatism. Where we have trauma to the abdominal wall sufficient to bruise the gut, it is also apt to prevent the muscles from becoming rigid. Just as in perforated appendicitis, the bowel is soft and the surgeon's attention is not called to that particular area until the patient has rallied sufficiently to have stiff muscles, and by that time it is too late to do any good.

W. C. Dugan: I would like for Dr. Willmoth to tell us his guide for operating in these cases?

A. D. Willmoth: I do not think the surgeon has any set guide. We have no accurate guide that will enable us to make the diagnosis early.

J. Hunter Peak: Like Dr. Abell, I have seen several cases of rupture of the intestine which were due to wheels passing over the abdomen. I remember one case in particular, in a boy 12 or 13 years of age, which illustrates the point brought out by Dr. Dugan in regard to shock coming on late. This boy was injured about four o'clock in the afternoon, the wheels of a heavy wagon passing over his abdomen, and, notwithstanding the large amount of trauma he sustained as revealed by operation at nine o'clock that night, he was able to get up and tell the people who gathered who he was and where he lived. He was taken home by a physician who happened to be passing, and who thought that the boy was not badly hurt. He did not exhibit symptoms of any severe lesion during the ride home. The doctor put him to bed and examined him, and found that he was considerably bruised on the left side just above the ileum. He told the mother that the child probably had a severe injury and that symptoms might develop later; not to feed him, but to keep him quiet, and if any symptoms developed to let him know. Two or three hours later the doctor was called and found the boy in pretty severe shock, and advised that he be sent immediately to the Infirmary where I saw him in consultation. By that time he was in profound shock, and it was a question in my mind whether or not it was due to hemorrhage. The abdomen was very tense and it seemed to me that a haematoma could be made out to the left of the umbilicus and between that and the crest of the ileum. Under warm packs and stimulants the boy rallied somewhat, and about nine o'clock that night we opened the abdomen in the median line, and I want to say that I never in my life saw so much trauma to the intestines as we found in this case. The wheels of the wagon had passed entirely over the abdomen, and there were any number of places where the intestines were bruised and blackened just the width of the wheel. The gut was torn entirely in two at the juncture of the descending colon

with the sigmoid flexure. This was repaired. The mesentery had been torn and tremendous hemorrhage had occurred. This place was closed, the gut stitched, and the patient put to bed in bad shape. He rallied somewhat and the next day was better, but died about forty-eight hours after receipt of the injury.

I remember another case in a woman who was thrown against a seat by the sudden stopping of a train. Shock occurred immediately in the case, just as though she had been struck in the solar plexus with a fist. Not much attention was paid to her condition at that time, but late after she had been taken home, she began to have hemorrhage from the bowel. I advised that an exploratory operation be done. This was refused, but she remained in the Infirmary for several days on a very light diet, and the hemorrhage ceased and she recovered.

We often see cases of gunshot and stab wounds, with severe injury to the intestine, but without any shock for some time afterwards.

Albro L. Parsons, (closing): I was considerably chagrined to feel that this patient had been under my care for twenty-four hours during which time I did not detect the fact that he had three ruptures of the intestine. This led me to look up the subject and after I had been making articles for about two weeks, I came to the conclusion that a good many men have done the same thing. It is appalling to think that one a slip and fall on the ice may result in a rupture of the intestine, as in Dr. Senn's case. As Dr. Willmoth says, we have no infallible guide in these cases; there is no symptom that is absolutely pathognomonic.

In a paper by Dr. Andrews of New York, he speaks of certain manufacturing plants where compressed air is used and says that when a new workman is employed, it is the custom of the others to "initiate" him on the evening of the first day. The "initiation" consists of throwing this compressed air, under a pressure of 60 pounds to the square inch, against the buttocks. This amount of pressure is sufficient to dilate the anus and the air rushes into the intestine, often causing a rupture of the large bowel. It has been shown that 8 to 10 pounds pressure is sufficient to rupture the large intestine. I did not take this phase of the subject in my paper, as it was intended to deal only with rupture of the small intestines. This is often caused by certain mechanical pursuits, such as receiving boards in a planing mill, particularly in the pine belt in the South. In the army, a kick from a horse is the most frequent occurrence, and in these cases multiple ruptures are nearly always found, occurring just at the points where the heels of the shoe strike the abdomen.

In conclusion, I wish to say a word of recommendation for the Library. When I began to look up the subject I obtained a lot of reference

and I was somewhat surprised to find that practically everything I wanted or needed was to be found on the shelves of the Jefferson County Medical Library.

VERTIGO.

By ADOLPH O. PRINGST, Louisville.

With the recent advances in the study of the anatomy, physiology and pathology of the internal ear by otologists, notably those of the Vienna school, our ideas of the significance of vertigo have materially changed. Though even now the physiology of the inner ear is not fully understood, it is practically agreed that the vestibule and semicircular canals have an important function in the maintenance of the equilibrium of the body. Just how the influence is exerted is as yet largely problematical.

It has been pointed out by Nagel that there is a whole series of dizziness forms ranging from one extreme of purely visual confusion to the opposite of mechanical rotational disturbance.

From my reading, I am convinced that there exists some difference in the interpretation of the term vertigo. While medical dictionaries probably without exception, employ the terms vertigo, dizziness and giddiness synonymously, I feel sure that the general conception of the term vertigo, is that it denotes dizziness in its superlative degree, and that giddiness is employed to express the condition in its mildest form. It is needless for me to state that vertigo in any of its forms or severity is but a symptom. It is frequently accompanied by such other pronounced symptoms, as disequilibrium, nystagmus, tinnitus, headache, vomiting and deafness, which aid in the differentiation of the various forms of vertigo and their causes.

Vertigo has been variously defined. Starr speaks of it as an uncertainty of position, attended by a sensation as if the body itself were being revolved in any one of its possible directions (subjective vertigo), or as if objects outside of the body were turning rapidly (objective vertigo). It has also been defined as a disturbance of the faculty of orientation creating a false conception or an illusion of ones relative position to space or motion.

It is now generally believed that the vermis of the cerebellum has to do with maintaining the equilibrium of the body by way of impulses passing to the cerebrum through its peduncles, and giving it the faculty of orientation, or the ability to appreciate one's position in space. It is also believed that vertigo with but few exceptions is the result of interference with the conduction to the cerebellum of certain peripheral or afferent impulses which are essential to the generation of the

new impulses going to the cerebrum and controlling orientation.

Recent study has demonstrated that ninety per cent. or more of all cases of vertigo are due to disturbance in the vestibular impulses resulting from ear diseases (Gowers). However, notwithstanding that the static impulses from the labyrinth are the most important afferent impressions governing orientation, the fact that after removal or destruction of one or both labyrinths, the equilibrium is regained, is evidence of contributory factors. These have been shown to be the impulse of sight and the so-called kinesthetic impulses which include the tactile, muscular and arthrodial senses. When these impulses agree, normal conditions prevail, but any discord between them brought on by interference with any one of them is accompanied by interference with orientation and the distressing sensation of vertigo.

In studying the various diseases and their influence over the afferent impulses to the cerebellum, we find but few instances in which the kinesthetic impulses are involved. Probably the best example is locomotor ataxia. It is believed that in this disease interference with the impressions is partially the cause of dizziness, but the chief factor is the interference with the impressions from the motorial organs (muscles and joints).

That the interference with one of the impressions which guide the center for the maintenance of equilibrium is not always associated with disequilibrium and vertigo, is exemplified in cases of locomotor ataxia, where, notwithstanding disturbed kinesthetic impulses, the equilibrium is maintained until the eyes are closed when dizziness prevails. In this instance the visual impressions help to maintain equilibrium and prevent dizziness.

A study of the influence of visual impressions upon the equilibrium center has shown that the impressions are not those of vision proper but that it is the projection of what is seen in relation to the position of the body. So we have in sudden paralysis of the ocular muscles vertigo (usually subjective), resulting from the seeing of two objects and an unconscious endeavor to distinguish between the false and true image. Vertigo also occurs when the patient is trying to sight or follow an object with a paretic eye. The patient locates objects wrongly, increasing proportionately as the paretic muscle is called upon in looking at them.

The net results of this false projection is that when he does use the paretic muscle or turn the eye, the objects that he sees, appear to move, and each at a different rate of speed, depending on its situation. This kaleidoscopic movement gives rise to a peculiarly unpleasant vertigo (Duane). In such cases vertigo

persists even though the nonparetic eye be closed, while the vertigo due to diplopia ceases upon closing one eye. Dizziness is perhaps seen more frequently in heterophoria or latent squint, than in all other conditions of the eyes. The vertigo which is at times observed in astigmatism, is believed to be due to reflex action.

Vestibular impressions which have to do with the equilibrium control emanate in the ampullae of the semicircular canals, the so-called static portion of the labyrinth. They pass by three tracts of fibres to the cerebellar centers governing equilibrium.

One of these tracts communicates in Deiters nucleus in the medulla with ocular fibres coming from the quadrigeminate bodies, one in another nucleus in the medulla with fibres which have to do with maintaining the muscle balance and another with fibres from the higher centers in the brain. It is now believed too that some fibres pass directly from the vestibule to the cerebellum without giving off collaterals. Disturbance of either one or the other tracts induces disequilibrium with associated vertigo and nystagmus.

Vestibular vertigo represents a large percentage of all forms of dizziness. It appears in varying forms, intensity and duration. It is either due to vestibular irritation increasing the excitability of the affected side or to vestibular destruction, causing superexcitability of the opposite side. It has been proven experimentally that the vestibular symptoms occur only when the preponderance of stimulation is on one side.

Clinical experience has shown that variations in pressure in the static ear is the most frequent factor in bringing about disturbed aural impressions by exciting the nerve endings. These variations may be due to intrinsic causes depending on primary conditions of the internal ear, or the influence may be transmitted from without through the sound conducting apparatus. As typical instances of this kind I would mention the vertigo frequently resulting from syringing the ear canal, from blows upon the ear, from sudden loud explosions, from the pressure of impacted cerumen or from living bodies, as flies and bugs getting into the ear canal. Vertigo accompanying a closed Eustachian tube is now generally believed to result from increased pressure exerted on the stapes by way of the ossicles and the drum membrane.

In middle ear sclerosis, the adhesions of the foot plate of the stapes and rigidity of the membrane of the round window is a frequent factor in increased vestibular pressure and vertigo. The large number of cases of chronic catarrhal otitis media, which come to us with tinnitus, deafness, vertigo and at times all of the symptoms which have been describ-

ed as Meniere's syndrome come under this category.

Less frequently an accumulation of fluid, either serous or purulent, the result of acute catarrhal or suppurative middle ear inflammations may create an increase in pressure.

Occasionally the inflation of air through the Eustachian tube is followed by a brief period of giddiness, evidently the result of momentary increase in pressure.

When vertigo occurs during purulent otitis media it is of serious importance, especially in the chronic cases. In these it may be due to the presence of pent-up pus, granulation tissue, or cholesteatoma, causing pressure upon the labyrinth. However, in most instances, vertigo occurring in the course of chronic suppurative otitis indicates involvement of the labyrinth itself through bone necrosis or pressure erosion as it occurs in cholesteatoma. Hence the development of vertigo in chronic cases accompanied by rapid decrease in hearing and with loss of bone conduction, is always a sign of danger indicating the probability of a labyrinthitis, either of the serous or purulent variety.

Instances of primary labyrinthian affections are infrequent. Meniere's disease which we know to be extremely rare is an apoplexy of the semicircular canals. It comes on suddenly in persons hitherto free of ear disease, has vertigo as one of its constant symptoms, and is associated with deafness, tinnitus, nausea, etc., and a brief period of unconsciousness. Toxic agents such as those arising in the course of mumps, typhoid, syphilis, etc., affect the vestibular apparatus primarily, or the auditory nerve, and bring about deafness and vertigo.

The belief is growing that practically all cases of vertigo with the exception of such rare conditions as specific disease affecting the auditory nerve trunk and primary cerebellar disease, as abscess or tumor, are of vestibular origin. Some believe that even those cases which supposedly are due to ocular and kinesthetic impulses, are really of vestibular origin, and that the ocular and kinesthetic impulses are simply the afferent stimuli which create the vestibular impressions. Many other conditions which were formerly described as producing vertigo are now looked upon merely as modifying or exciting factors, that would have no influence upon a normal ear. However, when any part of the middle or internal ear is not in a normal condition, the constant super-excitability of the static labyrinth causes it to respond readily to influences such as diminished or increased labyrinthian pressure and create an attack of vertigo.

Rhese, of Konigsberg, in a recent contribution to this subject, expressed the belief that the centers of the vagus and the vesti-

ular nerves lie close together and that this accounts for the frequency of nausea and vomiting in vestibular dizziness. The giddiness observed in derangement of the stomach or liver and the dizziness occasionally seen in irritation about the larynx, (laryngeal vertigo) are given as further examples. He also believes that a communication exists between the tri-facial and the vestibular centers and cites as evidence the vertigo produced by touching the upper and posterior portions of the ear canal and that observed in cases of hypertrophied turbinates in the nose.

By virtue of the proximity of the vaso-motor center to the vestibular nuclei he accounts for the tendency of individuals with disease of the vascular system accompanied by impairment and retardation of intracranial circulation to have attacks of vertigo.

We are all familiar with cases of endarteritis prior to apoplexy accompanied by ear noises when slight muscular efforts such as straining at stool brings on dizziness. Anything that will bring on cerebral congestion or anemia may bring on an attack, instances of which are seen in the early stage of meningitis or in epilepsy. In speaking of epilepsy, Gowers says that vertigo is the most frequent subjective evidence of an epileptic seizure. In fact vertigo may represent the arm of an epileptic attack. Owing to the features that the epilepsy and Meniere's disease have in common, the sudden onset, brevity of the attack, the tinnitus, frequent nystagmus, period of unconsciousness, etc., makes the diagnosis difficult during an attack. The persistence of tinnitus and deafness after the attack in Meniere's disease differentiates between this disease and epilepsy. Vaso-motor disturbance would also account for the cases of vertigo occurring at the menopause as well as the dizziness occasionally seen in neurasthenia and hysteria.

The vertigo so common in organic brain disease is now also believed to result from an increased intracranial pressure. In brain tumors, abscesses, hemorrhages, and softening of the brain, vertigo is a frequent symptom. There is usually but one attack as the equilibrium is regained by the aid of the other structures concerned in the muscle balance.

Transient attacks of dizziness frequently observed after the use of stimulants such as alcohol, coffee and tobacco, are generally looked upon as the result of vaso-motor disturbance as in the giddiness of uremic poisoning.

The differentiation between the various forms of vertigo is somewhat difficult, but is being simplified more each year. Considering first the vertigo due to affections of the kinesthetic sense organ, we have as diagnostic aid accompanying symptoms indicative of the disease (locomotor)

which brings on the disturbance of the kinesthetic afferent impulses and the disappearance of the vertigo when the patient assumes the recumbent position. The absence of ocular muscle defects and the persistence of the dizziness when the eyes are closed, would exclude ocular causes and the absence of nystagmus, deafness and tinnitus aureum would exclude vestibular causes.

Vertigo due to affections of the visual sense organs is recognized by the diplopia or when absent by muscle tests demonstrating muscle paresis or insufficiencies. Closure of both eyes relieves the symptom, while the position of the patient does not influence it.

Unless coincident ear trouble exists, there is no deafness or tinnitus and as a rule no nystagmus. The rotary vertigo and nystagmus occasionally seen in cases of parietic eye muscles is believed to be a reflex action through Deiter's nuclei.

Labyrinthian vertigo is always of the rotary variety and is accompanied by disturbed equilibrium and frequently by nystagmus, tinnitus and deafness.

It would be too far reaching in a discussion before a body of general practitioners to endeavor to differentiate between the various ear affections, for which the coloric and rotation tests are employed. However, I would call attention to the belief which is now prevalent, that many of the diseased conditions of the internal and middle ear keep the static vestibule in a hypersensitive condition, so that slight stimuli, such as increased blood pressure, toxic influences, etc., may bring on the dizziness. On the other hand it has been pointed out that even where there is a hypersensitive vestibule, vertigo may not be present, due to a compensatory action of the visual and kinesthetic senses and that a diagnosis can be made only by excluding one of these. With a hypersensitive vestibule and no dizziness with the eyes open, the symptoms prevail upon closing the eyes.

Vertigo due to disease of the cerebellum is recognized by other symptoms of this condition, as increased intracranial pressure and possible choked disc, by normal response to coloric ear tests and absence of tinnitus.

In considering the prognosis and treatment of vertigo, I am forced to the admission that a great majority of cases in which the symptom has been of long standing are incurable. The treatment naturally depends upon the underlying affection. Transitory attacks of giddiness due to intestinal disturbances, errors of refraction, etc., where the existing ear conditions are insignificant can be relieved by correcting these conditions. Vertigo due to defects in the ocular muscle balance may be relieved by correcting errors of refraction, by the use of prism or by surgical means.

Aural cases due to impacted cerumen are naturally easily relieved, as are the cases of transitory dizziness due to the accumulation of fluid in the middle ear, result of acute inflammation. The cases of persistent vertigo arising from diseases of the middle ear are relieved with difficulty. Where the closure of the Eustachian tube is a factor opening this by catheterization or the use of bougies may bring about relief or cure. Inflation and exceptionally massage of the ossicles has benefited cases due to the sclerosis of the middle ear. In the cases associated with high arterial tension, attention should naturally be directed towards the relief of this condition. Cases due to serous inflammation of the labyrinth either primary or occurring in the course of a suppurative middle ear inflammation have been reported improved by the administration of pilocarpine in increasing doses (from 5 to 10 drops of a 2 per cent. solution given every day) until a physiological effect is produced and the labyrinthine pressure is reduced. This treatment seems to have had special virtue in cases dependent upon syphilis.

Quinine in 1 grain doses several times a day has been used, at times successfully, to reduce the vestibular irritability, probably by overcoming congestive conditions. Bromides and iodides have also been employed with some favorable reports. Lumbar puncture has been employed by Babinski and others, but has fallen into disfavor, owing to the element of danger in its employment and the uncertainty of its result.

In patients subject to vertigo, excitement of all kinds should be avoided as far as possible. Diet should be simple. Alcoholics, coffee and other stimulants should be prohibited.

In extreme cases where the hearing was almost destroyed and life was made unbearable by the vertigo and tinnitus, Milliken and others have resorted to destruction of the labyrinth.

The suppurative cases of labyrinthian inflammation indicated by symptoms of destruction of the labyrinth are surgical cases and therefore come strictly under the domain of the specialist.

DISCUSSION.

Jno. J. Moren: I see a great many cases of vertigo, from those which result from going to the tops of high buildings in people who are very susceptible to height, down to the tabetic who has a great deal of difficulty in maintaining his equilibrium. Disturbance of equilibrium may come from one of three tracts, the eye, ear, or muscular senses, and in making my diagnosis I try to connect the condition with one of these three tracts.

I have seen a large number of cases of vertigo,

including even Meniere's disease. Last fall a man came to my clinic and spoke to me. I did not remember him, but upon talking to him I learned that he was a man who had been treated at the hospital clinic for a typical Meniere's syndrome, of syphilitic origin. Under the administration of iodides that man got perfectly well, and now has no evidence of vertigo, tinnitus or any other symptom. That is the best result I have had in any case of vertigo of an organic nature.

I have seen a number of cases of vertigo in women, particularly those with gastropnoia, and more especially at the menopause. These must belong to the aural group, resulting from disturbance of the vasomotor system and disturbance of circulation. Oftentimes they complain of tinnitus, but upon improving the circulation and correcting the anemia this usually disappears very promptly.

In regard to anemia, I would like to relate one experience I have had. This patient was a man who had undergone a mastoid operation and thereafter suffered a great deal from dizziness. I found him to be suffering from a secondary anemia, his haemoglobin being something like 60 or 70 per cent. Upon the administration of iron his anemia improved considerably, and he did not suffer so much from dizziness. In that case the anemia evidently played a part in producing the vertigo.

In regard to the differential diagnosis between vertigo and epilepsy, I do not believe this should be difficult if one will remember that epilepsy is a disturbance of consciousness, which may be accompanied by convulsions. We need not necessarily have convulsions to establish the diagnosis of epilepsy, but we must have a disturbance of consciousness. In vertigo the patient very seldom loses consciousness; on the other hand, we never see a case of epilepsy in which the patient does not lose consciousness, although it may be for only a moment. Those cases classed as Meniere's disease also never lose consciousness.

I think the essayist has covered the ground very well. Whenever I see a case of vertigo I usually send the patient to the ear specialist.

S. G. Dabney: It is evident that we are all somewhat at sea with our theories about vertigo, so I am going to leave them out.

I am not certain that we can classify all cases of vertigo under the three heads mentioned by Dr. Moren. It seems to me that we cannot eliminate the vertigo of toxemia, nor that due to arteriosclerosis affecting the nerve centers, even though the eye, ear and muscle centers may all be good. This was brought to my mind by a gentleman whom I saw late Saturday afternoon, who, some three or four weeks ago, was suddenly taken with an acute spell of dizziness and sick stomach, though there was no ringing in the ear. The family physician was sent for and he was

taken to his home. The doctor told him that he had an acute autointoxication. The acute symptoms passed off, but from that time to this he has been suffering with recurrent attacks of mild vertigo. I have seen several cases in old people, past sixty or seventy years of age, whose eyes and ears were in very good condition indeed for that time of life, and whose muscle sense was excellent, but who were subject to attacks of dizziness, due to increased pressure from hardened arteries. I do not see how we can put these cases into any of the three groups mentioned by Dr. Moren.

I think Dr. Pfingst might have emphasized a little more strongly than he did, the relation of diseases of the middle ear to vertigo. I recall one lady who had been under observation for eight or ten years for deafness in both ears. One ear had never suppurated while the other had been subject to suppuration ever since childhood. She came to consult me about her hearing, and complained of spells of dizziness with sick stomach. While she did not lose consciousness she would get so dizzy that she would right frequently fall on the street. She has never fallen since the time of her first visit to me. Upon examination I found cholesteatoma, or cheesy mass packed in the duct, which I removed. Had she lived in the country I would most certainly have recommended radical mastoid operation, but as she was a woman of unusual intelligence and lived in the city, I told her to come to see me from time to time and have her ear cleaned out. Her hearing has improved and she does not have any more dizzy spells. I saw another case in a man who came to me because of the fact that he had dizzy spells and was afraid that people would think he was drunk. His ear was washed out and he got all right.

I was glad to hear Dr. Pfingst say that where there is no tinnitus, no deafness and no nystagmus unless produced by some means such as the rotation test, he does not look upon the case as aural. Like Dr. Pfingst, and opposed to the opinion of some of the great authorities on the subject, I cannot bring myself to believe that in persons who hear well, whose drum membrane is perfect in appearance, and who have no ear symptoms whatever, the trouble is of aural origin. We are not going to help these cases by treatment directed to the ear. I have not used pilocarpin in these cases. Pilocarpin is a great drug to promote absorption, but I have never used it in the ear. It is recommended, not only in suppurating middle ear disease, but in acute labyrinthian troubles, chiefly as a means of producing rapid absorption. I do not think we can accomplish much in internal ear disease. We can however, accomplish a great deal in middle ear disease which is often a cause of vertigo.

Ocular vertigo may be relieved very frequently by means of prisms, as well as by correcting errors of refraction. A few weeks ago I treat-

ed a man for this condition with prisms. He was going to Florida the next day, and I told him I was not certain about the results, but he informed me that they worked all right; that he did not have any more dizziness or double sight.

I cannot get away from the idea that, practically, at least, we have to go outside of the eye, ear and muscle centers to ascertain the cause of vertigo.

C. G. Forsee: I would like to ask Dr. Pfingst to tell us in closing what the cause of vertigo in elderly people usually is. I have seen a good many patients who have what they call "schwindel." Nine out of ten will say that while walking, as long as they look where they are going they are all right, but let their attention be diverted for a moment they experience a sense of dizziness. In only one case of this kind have I been able to find impacted ear-wax as the cause of the trouble.

Herbert Bronner: There is just one point in connection with this subject that I wish to mention. Since the introduction of Salvarsan in the treatment of syphilis, quite a number of cases have been recorded in which nausea, vomiting, loss of hearing and vertigo followed its administration. In the beginning the claim was made, especially by those who were over-enthusiastic in regard to salvarsan, that this group of symptoms was always due to the syphilitic trouble, yet men who treat hundreds of cases of syphilis rarely ever see a case of acute labyrinthitis due to syphilis. In more recent literature it is claimed by some men that these symptoms are probably due to the salvarsan itself. Only recently I read an article by Dr. Ernest Finger, of Vienna, in which he claims to have found nerve lesions in 9 per cent. of cases following the use of salvarsan, which he believes to be due to the salvarsan. I have seen only one case of this kind, in a young woman who was given "606" for the secondary eruption. Eight weeks later she developed a most intense vertigo, accompanied by nausea, vomiting and loss of hearing. I gave her the ordinary mercurial treatment, and in six or eight weeks these symptoms disappeared. Personally, I am inclined to believe that salvarsan is a factor in the development of these intense vertiges. I would like for Dr. Pfingst to speak to this point in his closing remarks.

Gzylord C. Hall: I wish to show a specimen and report a case in connection with this subject. This case illustrates the type of vertigo found in acute infection of the labyrinth, with destruction of the labyrinth and complete loss of hearing.

I saw this man, who is 35 years of age, about a year ago. In the early part of December, 1910, he was seized with a violent attack of vertigo, with pains in the head, nausea and vomiting. He was treated by the family physician for a bilious attack, being compelled to stay in bed, on account of the vertigo, for nearly two weeks. As

long as he was in a recumbent position he was all right, but when he attempted to walk he had a staggering gait. He was sent to me for correction of a possible error of refraction. He was wearing glasses. I accidentally noticed that he had a plug of cotton in his ear, and upon questioning him in regard to this, I learned that at the onset of the attack described, he had had considerable bloody discharge from that ear, and examination showed the canal to be full of a stinging, bloody material. He was totally deaf on that side. The canal was filled with polyps and granulation tissue. I advised radical mastoid operation, as the labyrinthitis had run its course, but he declined an operation. Dr. P'ingst saw the case and also advised radical mastoid operation, which he again refused. However, he was on very regular treatment, and some weeks later he came to my office and said, "Doctor, here is something that came out of my ear," and handed me the specimen which I herewith present. It does not take much stretching of the imagination to say that it is the apex of the cochlea. Evidently the infection had gone through the middle ear and invaded the labyrinth and internal ear, notwithstanding which the man did not develop meningitis and the inflammation finally became encapsulated. I hear about a month ago that he considered himself entirely well. Whether that is true remains to be seen, but the case illustrates how beautifully Nature cures for these cases at times. This man has no vertigo at the present time.

W. T. Bruner: One cause of vertigo that has not been mentioned is sudden rupture of the drum membrane. I saw a case some time ago in a man who, while working at a circular saw, fell forward, barely missing the saw. Examination revealed a ruptured drum membrane. This man had been complaining for several days of a slight attack of gripe. After the rupture of the drum there was a very slight discharge. The vertigo in this case was caused by the sudden rupture of the drum membrane. I report this case because in an attack of vertigo coming on suddenly as in this case, the cause may be overlooked unless the ear is very carefully examined.

F. T. Fort: I am very glad to have heard this paper, but was sorry that some treatment for vertigo was not given. I was called to see a woman to-day and found her almost in an attitude of prayer, and she said that that was the only position she could get in that her head did not swim. I have seen four similar cases in the past few months. Just after Christmas I was called to see a woman whose principal symptom was vertigo. Five or six days later she became unconscious and died two days later. Dr. Frank and Dr. Moren saw her with me. This was probably due to arteriosclerosis, and in this class of cases no form of treatment seems to give good results.

B. F. Zimmerman: I was glad to hear a paper

by a specialist who holds such conservative views as those expressed by Dr. P'ingst. So often there is a tendency to attribute practically everything to the particular group of organs which we may be interested in treating.

I think the point made by Dr. Dahney is well taken. The maintenance of equilibrium is purely reflex. We have three channels by which the afferent impulses enter. These are received by centers, or fibers, which alter or change the impression and send out those pertaining to the movements of the body. Now, we may have disturbance of either of these channels through which the afferent impulses enter, or of the classification and distribution centers. In this way I think many cases of vertigo in old persons, due to lesions in the brain, arteriosclerosis, etc., may be accounted for. Again, toxic conditions may affect the centers which have to do with the altering of impulses and sending them out along other channels.

The ear is probably the most important factor in the production of chronic vertigo. The eye is of less importance. Most of the cases of vertigo that I have seen have been connected with the vagus. Dr. P'ingst has explained the close relationship existing between the vagus center and the vestibular branch of the auditory nerve. The determination of the exact site of the lesion is not easy. Therefore, I think that if the general practitioner, after having exhausted all the ordinary tests, is not satisfied, he should send these cases to the specialist for careful examination of the eyes and ears.

The treatment of chronic vertigo is very unsatisfactory. However, in acute conditions, either of toxic or gastro-intestinal origin, satisfactory results may be obtained from treatment.

Bernard Asman: About a year ago a man, 40 years of age, who had been suffering with vertigo for a number of months, was referred to me, not because of the vertigo but because he was also a sufferer from chronic constipation of a very pronounced type. Upon sigmoidoscopic examination it was at once apparent that he had disease in the sigmoid, probably due to long-continued pressure from hard fecal matter. He presented symptoms of toxemia, and responded nicely to treatment so far as the bowel was concerned. His vertigo had been very severe. He said that he tried to avoid crowds of people, because his vertigo was always worse when in a crowd than at any other time, and that when he came to a crowded street he would wait until but few people were passing before trying to make his way across. Treatment of the chronic constipation was followed by apparent relief of the vertigo. After several weeks he concluded to go to a certain health resort for treatment, and when he had been there a few days I received a letter from a doctor of that place, stating that he had discovered the specific cause of the vertigo, which was due to impacted cerumen, which he

had removed, and said that the vertigo would be permanently relieved. However, a few weeks later the patient came to me and said that the relief had been more imaginary than real and that his vertigo was almost as bad as before. I treated him for chronic constipation for some months longer and as that got better the vertigo almost disappeared. I have not heard from him for two months, but at the last report his condition was very good indeed.

Adolph O. Pfingst, (Closing): I want to apologize for not bringing a more practical subject before the society.

I took up the subject vertigo, because its etiology is rather obscure and its treatment so unsatisfactory. It was in the hope of eliciting an instructive discussion.

I agree with Dr. Dabney that in a certain number of cases, where occlusion of the tube is the cause, we can give them relief by equalizing the pressure in the tympanic cavity. We can also relieve the condition when dependent upon the presence of fluid in the middle ear. Those cases due to impacted cerumen are naturally easiest to relieve.

In the absence of pronounced symptoms denoting ear trouble, I eliminate the eyes first, because we have quite a number of eye conditions that may give rise to vertigo. Failing to find the cause in the eyes, I then make careful examination of the ears, but am free to confess that I am frequently not able to find the cause of the symptoms.

The question in regard to old people has already been answered, since in these patients it is usually due to arteriosclerosis. We are all familiar with this condition, which is considered a forerunner of apoplexy.

As to Dr. Bronner's case, I do not know what could have produced the vertigo. I know that Dr. Beck, of Vienna, who has been very much interested in syphilitic conditions of the ear, reports a number of cases of vertigo cured by the administration of "606", but I do not know of any case where vertigo was produced by it. Although nerve deafness has followed its use,

left, but returned in August, 1911. His family history was very vague, but it appears that his father died of carcinoma of the stomach, although it cannot be said positively that such was the case.

The symptoms this man presented were very similar to those of gastric ulcer. He suffered considerable pain which was relieved by the ingestion of food. He had vomited almost daily during the entire time he had been at the hospital. Examination of the stomach contents showed an almost entire absence of hydrochloric acid. Examination for occult blood in the vomitus or stools was not made. No evidence of induration about the stomach could be detected upon palpation. I advised exploratory operation, believing that we would find a gastric ulcer, and that a gastro-enterostomy would probably have to be done.

When the abdomen was opened and the pylorus exposed it was found that, although flaccid and soft, there was no evidence of constriction. Upon exploration with the finger along the lesser curvature of the stomach, I discovered an indurated mass of considerable size, probably two-thirds of which was behind the gastro-hepatic omentum, the remaining portion presenting on the anterior portion of the stomach. This tumor, when removed, proved to be about the size of half an orange. It was entirely covered by adhesions which had grown out from the omentum upon the posterior surface of the stomach, which made it somewhat difficult to separate the tumor. The tumor was excised by simply making an elliptical incision and cutting it away with scissors. The stomach had been washed out before the operation and was practically entirely empty when the operation was done. A drainage tube was introduced as a matter of precaution, and the sinus remained open for three or four weeks after the operation. It was not a fistula; no stomach contents escaped through it, but simply a secretion which was apparently caused by the cicatrization.

This operation was done on October 30th, since which time the patient has gained eight pounds in weight, and can now eat almost anything he wants. He has not vomited since the operation. I have brought this man here to-night simply as a corroboration of the statement that, from an emaciated and feeble individual prior to the removal of this growth he has regained his strength and appears to be entirely restored to health. Of course, it is still too early to say whether or not he will have a recurrence of this condition. No microscopic examination of the growth has been made. The chief reasons for the diagnosis of malignancy were, the absence of hydrochloric acid in the stomach contents, and the fact that the patient had become greatly emaciated without there being any obstruction

CLINICAL CASES AND SPECIMENS

REPORT OF CASES.

By H. H. GRANT, Louisville.

CASE I.—CARCINOMA OF LESSER CURVATURE OF STOMACH.

(PRESENTATION OF PATIENT AND SPECIMEN.)

The patient I herewith present is a man whom I first saw at the City Hospital, during the service of Dr. J. Rowan Morrison, with the following history: He had been in the City Hospital about a year previous to this time for some trouble referable to his stomach. He remained there for some time and then

of the pyloric orifice. The food he took was simply arrested in the stomach and did not pass out.

CASE II.—PERFORATED GASTRIC ULCER.

I saw this patient in April, 1911, with the following history: The physician who had attended him found him lying upon the floor, screaming with pain. He had been complaining of pain in the region of his gallbladder and liver for some months, but had never had an attack as severe as this one. It required two hypodermics of morphine, at intervals of three hours, to relieve him. The pain was not unlike that attending the passage of a kidney stone. After the second hypodermic he slept all night, and the next day seemed to be in pretty good condition. Following this attack he had no evidence of inflammation or peritonitis, nor any pain beyond a little discomfort and soreness, and was able to go to work. When I saw him about three weeks later, he was again complaining of pain in the region of the gallbladder, and upon examination I found him to be markedly tender all around the gallbladder. I made diagnosis of gallstones, and persuaded him to undergo an operation for their removal. He went to the Infirmary and a day or two later incision was made and the gallbladder exposed, but nothing abnormal was found in it. It was perfectly healthy and contained only a moderate amount of bile. No stones could be detected upon palpation of the gallbladder and it was not opened. Upon exploring a little farther with my finger, I detected a great many adhesions over the anterior surface of the stomach, and upon separating these I found a little opening in the stomach just about large enough to admit a lead pencil. This, to my mind, explained the severe pain the man had suffered. Undoubtedly, the perforation had occurred at the time of this attack. There had probably been only a very small amount of leakage, and the opening had then been covered up by omentum and he had no further trouble. This was probably an old ulcer, which had existed for a long time and had just worked through.

The ulcer was completely excised by an oblique incision, and the stomach walls approximated with three layers of sutures in the same way as the previous case reported.

One interesting feature of the case was the fact that I uncovered the ulcer while separating the adhesions with my finger. If it had happened that I had not seen it, if I had supposed that I was simply breaking up adhesions which we so frequently see in the region of the gallbladder and had not observed the perforation, this man would have had peritonitis and there would have been an unexplained death. Adhesions are frequently

seen after inflammation of the gall-bladder, and in many instances the operator stops short when he finds extensive adhesions, and in breaking these up he may, if he is not very careful, overlook a condition of this sort, and open up communication between the intestine and the stomach, which will result in the death of the patient.

DISCUSSION.

J. Rowan Morrison: I first saw this man in October, 1910, during my service in the City Hospital. At that time he presented some stomach condition, and had emaciated considerably. Vomiting occurred usually at what was considered the height of the digestive process. At that time he suffered a great deal of pain and there was considerable tenderness over a localized area in the epigastrium. Analysis of the stomach contents showed an excess of hydrochloric acid. Oftentimes he would obtain relief upon taking a little milk. In a number of cases of this character I have used orthoform, and if I remember correctly, this man was relieved by orthoform. I considered at that time that he had an ulcer of the stomach, and advised operation which he declined, and left the hospital, but returned about a year later. During the interim he had emaciated a great deal. He gave a history that during this time the vomiting had continued, and that he had suffered considerable pain upon the ingestion of food. This continued after he returned to the hospital. I recall that, on several occasions, I ordered that he be given a meat meal at night, raisins, etc., in order that we might ascertain the next morning, by examination of the stomach contents, whether or not there was much stagnation, but he was not able to do even this because of the pain it caused him. He was given an ordinary water and bread meal, and two hours later he vomited it, and this specimen showed practically no hydrochloric acid, with diminished total acidity. One peculiar thing about this case was the fact that, while there was no stenosis of the pylorus, he had considerable dilatation of the stomach. He could easily take a gallon of water before he complained of pain, and this water would be returned. Also, inflation of the stomach with gas showed it to be greatly dilated. I advised operation, which was accepted, and Dr. Grant has shown you the excellent results obtained from operative procedure in this case. It should have been done a year previously. Whether this growth is a carcinoma or not, I do not know; it looks very much like it. I feel that this was primarily a case of ulcer, and that the carcinoma was engrafted upon it, and that if he had been operated upon when I first saw him, we would have found an ulcer, because the symptoms of acute ulcer were then much more marked than at the time he was operated upon. No test was made for occult blood at the time of operation, but I remember that, on the previous oc-

case, analysis of the stomach contents showed the presence of blood.

J. Garland Sherrill: These cases are exceedingly interesting to me. It would appear, from the additional history given by Dr. Morrison, that the first case reported was on the border line, or in the pre-cancerous stage. It is an unquestionable fact that in the presence of a gastric ulcer we have an increase in HCl, and in the latter stage have an absence of HCl in the stomach contents.

As to the dilatation of the stomach, mentioned by Dr. Morrison, it occurs to me that this may have been the result of spasm of the pylorus caused by irritation of the pylorus produced by the ulcer. In several cases that I have seen, where the ulcer was situated nearer to the cardiac end of the stomach than the pylorus, there was a tendency to vomit food within a very short time after its ingestion; in other words, the motor activity of the stomach was increased, probably due to irritation by the ulcer. Therefore, where the ulcer is situated near the pyloric end of the stomach, the irritation produced thereby would have a tendency to cause pyloric spasm, resulting in dilatation of the stomach.

In regard to the second case, I think the point made by Dr. Grant, that we should make a very careful search for possible points of leakage in all operations in the upper abdomen, is a very valuable one. I can recall two cases in my experience where this point was very forcibly impressed upon me. One was a case of gunshot wound of the abdomen, the bullet just grazing the spleen and, as it proved at postmortem, perforating the stomach. This patient died of peritonitis, and at post mortem a minute opening was found in the cardiac end of the stomach. It was so small that it could hardly be detected, and gas would not escape through it when the stomach was pressed upon.

In another case the patient had evidence of acute peritonitis in the upper abdomen, which I took to be due to a perforation in the upper intestinal tract, possibly the stomach. A search was made for a leak but none could be found. The appendix was examined and found to be perfectly normal. Upon making a second search, however, we discovered a punched-out perforation of the duodenum, about the size of the hole made by a shoemaker's punch, through which fluid was escaping into the abdominal cavity. It was only after the most careful search that we were able to find this opening.

It has been astonishing to me at times to find how large an ulcer of the stomach can exist for a long time without rupture. I remember one case of this kind who went along for two years or more with the usual symptoms of ulcer of the stomach, and finally died from a rupture of the peritoneal coat. Post mortem showed the ulcer to be more than three inches in diameter, while the rupture was less than an inch in diameter.

Evidently this man had been carrying around for several months an ulcer that involved two coats of the stomach, the contents being retained by the peritoneal coat alone.

W. H. Wathen: I doubt if this specimen will prove to be a carcinoma upon pathologic examination, but if it does not, it will be an advantage, because the operation will then have been a timely one and the patient will probably remain well.

A condition of this sort, if not already carcinomatous, will almost certainly become so. It has been shown, by pathologic examination of specimens of cancer of the stomach that have been removed, that from 65 to 70 per cent. of these growths develop in the base of a chronic ulcer. It has also been shown that it is practically impossible to make a diagnosis of cancer of the stomach from physical examination, or from laboratory analyses of the stomach contents. Therefore, operation should always be done in cases where there is a well-marked chronic or enlarged ulcer of the stomach or duodenum. The history in well developed cases is generally so characteristic that diagnosis can be made even without analyses of the stomach contents, but in a city of this size, with the ample facilities at our command, we should confirm our diagnosis by chemical analysis of the stomach contents before operating. However, in suspected carcinoma of the stomach, we should not wait upon chemical analyses of the stomach contents, nor any other form of laboratory work, because, if we depend upon these analyses for our diagnosis, the patient will in all probability get beyond the point where we can give him permanent relief either with or without an operation. Even though the growth itself may be removed, the disease will have progressed so far that it will soon return.

Dr. Grant stated that, in his case, he based the diagnosis of carcinoma upon the fact that one or two examinations of the stomach contents showed an absence of free HCl. We know that nearly all the acids and pepsin are secreted at the pyloric end of the stomach, and as that portion of the stomach was in relatively good condition in this case, there should not have been very much interference with the secretion of HCl.

The second case reported by Dr. Grant appears to have been one of protected perforation of the stomach; where the ulcer gradually necrosed the tissues down to the peritoneum, but before it had completely perforated, plastic exudations were thrown out, attachments to other structures formed, and the patient never had an open perforation. I think Dr. Grant did right, in this case, in separating the adhesions and suturing the stomach. However, I do not think it is necessary, as a rule, even in open perforation of the stomach to trim off the edges, unless they are ragged and rotten. They will grow together just as well if sutured directly through all the tissues down to the mucous membrane; and then throw one layer of celluloid thread or silk over it; I do not think

two layers are necessary unless there is some imperfection in the line of sutures. It is also good surgery to suture the gastro-colic and gastro-hepatic omenta over the closed perforation, and have done this for several years.

Louis Frank: I am inclined to believe, from the size of this tumor and the length of time it had existed, that it is malignant. However, this question can only be determined positively by microscopic examination. I have removed growths of the stomach, believing them to be malignant, when microscopical examination showed that such was not the case; on the other hand I have removed sections of the stomach for what I thought was ulcer, and microscopic examination showed them to be carcinomatous.

These are two very interesting cases. I must differ with the last speaker in one of the statements he made. I believe that any erosion of the stomach may cause pyloric spasm; and thus produce dilatation of the stomach.

In discussing these cases I have only one criticism to offer; that is, in the first case reported, this patient should not have been subjected to excision of the growth, but resection, including the gastro-hepatic and gastro-colic omentums. I do not think we should be satisfied with merely excising the growth in such cases as this, because, if any lasting good is to be obtained, it must be by wide and free resection. In all of these cases, even where there are well developed carcinomatous growths, after removing the cause of the pyloric obstruction, whether it be by gastro-enterostomy or any other operation which permits the escape of food from the stomach into the lower bowel, these patients usually show an increase in weight, extending over a period of several months; in fact, some of them will increase in weight for a considerable time and then die very rapidly, in the course of a week or two, without showing very much loss of weight.

I also differ with the last speaker upon another point. He stated that a large percentage of gastric carcinomata have been found to have been engrafted upon old ulcers, which I believe is a fact that is now generally accepted. Therefore, I believe that we make a radical error if we do not excise these ulcers in the presence of perforation, instead of simply draining and sewing them up. When there is already an opening into the stomach, there is no excuse for not excising the ulcer, and I do not believe we are doing our full duty to our patient if we allow it to remain.

I was very much astonished at the remarks made by two or three of the speakers in connection with the second case reported. It has been my experience and observation that whenever adhesions are found upon any of the abdominal viscera, it has been customary to make a very careful examination for possible perforations and peritoneal denudation after these have been broken up. I think the real lesson to be learned

from this case is that the stomach contents are highly infective. It has been shown that, after starvation for a few days, the empty stomach is practically sterile, but when food is taken the bacterial count rises very high, and, furthermore, that when the process of digestion has been completed and the stomach is again empty, it becomes sterile in a very short time. I think this explains the fact that in many of these cases of gastric ulcer with perforation we find that secondary adhesions have formed, and death does not always follow.

Geo. S. Coons: Referring to the first case reported, I would like to make the history of this patient complete. It seems that he has suffered at the hands of many physicians.

This man was in the hospital during the service of Dr. Underwood, about ten months ago. At that time he was able to eat anything he wanted and was not vomiting at all. Gastric analysis was made, but nothing wrong with his stomach could be noted at that time. He had come to the hospital for a chronic diarrhoea, which had existed for three or four weeks. This was relieved by appropriate remedies, I believe, but he continued to have repeated attacks of high temperature, every few weeks, running up to 104 or 105, which would drop upon the administration of quinin. However, the point I particularly wished to call attention to is the fact that, ten months ago, this man had nothing wrong with his stomach, judging from the gastric analysis and the way he was eating.

H. H. Grant, (Closing): I have nothing further to say. I stated in the report that I thought this was an ulcer before I operated, but that the macroscopical appearance of the growth after it was removed led me to believe that it was malignant. Of course, this cannot be determined positively without a microscopical examination.

SOME UNUSUAL OCULAR CONDITIONS.

By ADOLPH O. PFINGST, Louisville.

A number of unusual cases which have recently come under my observation may, on account of their infrequency, be of some general interest. Believing that a detailed description would be of interest only to men doing special work I will endeavor to make my report as brief as possible.

PHTHIRIASIS PALPEBRARUM.

A case of phthiriasis palpebrarum or the presence of ordinary crab lice (*pediculus pubis*) on the eye lashes. I saw this recently in a child of four, this being the sixth time that I have observed the condition in my private practice. Strange to say the children in all but one instance were of good family, and apparently cleanly. The condition is characterized by itching and redness of the eye lids, and resembles marginal blepharitis, and in

consequence is easily taken for this disease. While the pediculus pubis like the other forms of pediculi, usually confines itself to its particular territory.—I feel sure that it occurs more frequently in the eye lashes than is generally recognized. It is a strange fact that this parasite does not invade the hair of the head.

Attention is called to the condition of the eye by the steel gray deposit at the base of the lashes, due to the presence of the ova of the louse. Close examination usually reveals the presence of one or more of the grown parasites clinging to lashes. Penciling the edges of the lids with a bichloride of mercury solution 1-500, or the application of mercurial ointment usually relieves the conditions promptly.

MUMPS OR ACUTE INFLAMMATION OF THE LACHRYMAL GLAND.

A case of mumps or acute inflammation of the lachrymal gland. This occurred in a healthy young man with no history to indicate its etiology. The upper lid of the left eye near the outer canthus was very red and swollen causing the lid to droop and entirely close the palpebral fissure.

The region of the lachrymal gland was very tender to the touch. The inflammation subsided with no other treatment than the application of heat, the lid returning to normal in about three weeks.

ARCNESS OF LEFT LACHRYMAL GLAND

Non-suppurative inflammation of the lachrymal gland is rather an unusual condition. I have seen but one other case of it. The

condition is analogous to parotiditis (mumps) and in fact is said at times to occur coincident with it. Its etiology is obscure.

While most cases terminate in perfect recovery, permanent enlargement of the gland has resulted while some have gone on to suppuration.

Several years ago I had occasion to see an abscess of the gland at the City Hospital, pictures of which I will exhibit.

SPONTANEOUS PROLAPSE OF THE LACHRYMAL GLAND.

Another infrequent condition of the lachrymal gland of which I saw a case recently is its spontaneous prolapse. It occurs usually as a result of inflammatory conditions of the conjunctiva or cornea and with the upper lid everted is recognized as a soft movable mass under the lid near the outer canthus.

CONGENITAL PARTIAL ANKYLOBLEPHARON.

I recently had a case of this kind brought to me from Shepherdsville for operation in which the baby's lids on both sides were adhered to each other by their edges, leaving a very small palpebral slit, through which the cornea was barely visible. The lids were separated with scissors and conjunctiva and the skin of the lids sutured.

COMPLETE SYMBLEPHARON.

A case of complete symblepharon in an adult following burn with molten lead.

Partial cohesion of the palpebral and bulbar conjunctiva following injuries or ulceration are not infrequent. Complete adhesion, as far back as the cul-de-sac and covering the cornea is uncommon.

I am reporting a case of this kind more especially to point out the hopelessness of such cases.

Partial symblepharon is easily treated surgically by severing the adhesions and covering the exposed surfaces with conjunctival flaps. However, where the adhesion includes the cul-de-sac, it is impossible to prevent reunion as two opposing raw surfaces which meet at an acute angle, invariably close again from the angle outward until the entire surfaces are again united. In the case which I am presenting to-night, I was urged by the patient against my better judgment to give him the benefit of a chance. With the exception of a pin-point opening at the nasal end the lids were grown together and to the eye ball.

By throwing light against his lids he could readily tell light from darkness and recognized the direction of the light, and it seemed that an operation must help him.

I performed the operation of Harlan. The lids were separated from each other and the lower lid severed as well as possible from the

eye ball. A flap was then made about 3-8 in. below the margin of the lid and turned upwards through an incision just above and parallel to the base of the flap bringing its raw surface against the inner surface of the lid. The upper lid was to be operated on later if the lower proved successful. As is the history of all similar cases adhesion between the eyeball and lid took place from behind, crowding the transplanted skin forward and finally closing up the fissure again.

COMPLETE OPHTHALMOPLÉGIA EXTERNA.

About six weeks ago a man of 24 years, in good health and giving a negative history of lues, presented himself with complete bilateral ptosis and paralysis of all of the extrinsic muscles of the eye of four years' standing. Both eyes were directed forward and there was total inability to rotate the eye balls in any direction. The intrinsic muscles were not involved as was evidenced by the nativity of the pupils and the ability to accommodate.

OPHTHALMOPLÉGIA INTERNA.

About a week after I saw this case, a man 23 years of age presented himself with an ophthalmoplegia interna. The pupil of one eye was wide, not responsive to light or convergence and inability to see close objects (loss of accommodation) while the extrinsic muscles were not involved.

Ophthalmoplegias are nearly always central in origin and are believed to be due almost without exception to changes resulting from inherited syphilis. Neither the internal or the external variety is common, although of the two the internal is the most frequent. It occurs practically always as a monolateral condition. Total ophthalmoplegia in which all of the extrinsic and intrinsic muscles are paralyzed occurs but is very infrequent. Grunert, of Bremen, has recently reported seven cases of ophthalmoplegia interna due to ethmoid disease which were cured by opening up the ethmoid labyrinth. He believes that in these cases the short root of the ciliary ganglion is directly involved in the inflammatory process.

In addition to these cases I will merely mention three other rather infrequent conditions which I saw at my office in the last weeks. *Congenital chromatic asymmetry* where one iris is brown the other blue, and a case of *congenital coloboma* of the iris or fissure of the iris resembling an iris after an iridectomy. Both of these conditions are not infrequent and have probably been seen by most of the members.

The third case was one of *argyrosis*, or discoloration of the conjunctiva following the prolonged use of argyrol. While I have in mind some other unusual eye conditions and

could find more by referring to my records, I have endeavored to confine myself to cases of recent observation.

DISCUSSION.

W. A. Jenkins: Just a word in regard to the first case reported. I was recently told by a physician whom I have known for a number of years that crab lice are very common among the poorer classes of Mexican children, usually being found in the eye-lashes and around the margin of the hair. Some time ago, in a local charitable institution, a nurse called my attention to the fact that one of the new entrants had a new kind of lice, and upon examination I found the head for a margin of half an inch, all around the hair line, literally alive with these lice.

Siegel C. Frankel: Just a few words in regard to the first case reported. In my work as inspector of schools, I have run across at least six cases of this condition. I am satisfied that I saw several cases last year, which I was unable to recognize until I found the live bugs on the lids. I noticed that these pediculi have a different color from that of the head lice, the former being dark-brown in color while the latter have a grayish appearance. I agree with Dr. Pfingst that they are found principally among children of the better class. All the cases I have seen were in this class of children. One was the grandson of a physician, to whom I wrote several letters calling attention to the condition, which he was unable to recognize until at last I was able to point out what actually existed.

S. G. Dabney: It is not very rare to find persons with differently colored eyes. It was said of one of the greatest of English actresses that she had one eye for comedy and the other for tragedy; one was blue and the other brown.

I have never seen a case of total symblepharon, and I wish Dr. Pfingst would tell us the exact condition of the cornea in his case. Did I understand him to say that the lids were adherent to the cornea?

I have had one successful result in a condition in which we are so often unsuccessful; namely, sarcoma of the orbit. About five years ago I removed the eye and orbital contents of a young lady for sarcoma back of the eye-ball, and, unusual to say, she recovered. I do not think there could have been any mistake in diagnosis, as one of my colleagues here concurred in the diagnosis and it was confirmed by two microscopic examinations. She came back last summer, very anxious to have a glass eye, which I did not believe would be satisfactory. However, I did a skin grafting operation and, following the advice given by one operator, I fastened the skin over the glass eye and put it in the socket. It took very well. The graft remained and the woman is wearing the glass eye tolerably well. Three months later I wrote to her doctor and asked about the result, and he replied that it was very

satisfactory and that the young lady had married. The trouble in these cases is from subsequent contraction, and I would not be surprised if, in the course of time, the result is not so good as it seems to have been in the first three months.

A word about the case of ophthalmoplegia externa. Dr. Pfingst said that his patient could not move the eye in any direction, but I fancy that he could have moved it downward and outward had the attempt been made. Otherwise it would mean that both the sixth and third nerves were involved, which is extremely rare. On the other hand, it is a familiar picture to see patients with dilated pupil, loss of accommodation, lid droop, and immobility of the eye, except that because the external rectus is supplied by the sixth nerve, the patient can turn the eye downward and outward. The vast majority of these cases are syphilitic in origin, though perhaps not invariably so.

It seems an odd thing to say that complete paralysis of the nerve offers a more favorable prognosis than some of its fibres only, but it is true in paralysis of the motor oculi because paralysis of the whole nerve is generally due to pressure along its course, while paralysis of some fibres only as, for instance, those which contract the pupil, are apt to be nucleated. When we see a patient with a dilated pupil which does not respond to light, we are apt to think that there is some disturbance in that particular bundle of fibres supplying the sphincter of the iris, and I do not recall having seen a case that got well. On the other hand, in the familiar picture of drooped lid, loss of accommodation, eye-ball turned slightly downward and outward, with inability to turn it in any other direction, these cases generally recover. I think it is very unusual, however, to find both the sixth and third nerves involved and that is the reason I believe that, if Dr. Pfingst's patient had attempted to move the eye downward and outward, he could have done so.

Adolph O. Pfingst, (Closing): Just a word in reply to Dr. Dahney. This case was very unusual. I am quite sure that there was involvement of the superior oblique and external rectus, as well as the muscles supplied by the third nerve, as there was absolute inability to turn the eye in any direction.

There was no involvement of the muscles of accommodation, the patient being able to read fine print. The pupil was of normal size. The patient gave a negative specific history.

In regard to Dr. Frankel's remarks, I will say that the crab louse differs in shape as well as in size from the head louse. It is smaller than the head louse and is rather round, or disc-like, while the head louse is oval.

ATROPHIC CIRRHOSIS OF LIVER.

(REPORT OF CASES.)

By J. ALLEN KIRK, Louisville.

CASE I.

G. K., white; age 44, admitted to the hospital on October 10th, 1911.

Past Medical History: Had rheumatism; had malaria five years previous to admission to the hospital.

Personal History: Denied specific disease; had drunk steadily for years, taking about three drinks a day at regular intervals, usually before meals; mostly alcoholic beverages.

Present disease began five weeks previous to admission to hospital, with pain in neck; pain jumped about over the body. Had had swelling of the foot. Vomited in the morning; had vomited blood on three occasions. Patient much emaciated, hepatic facies, was jaundiced; abdomen much distended. The superficial veins over thorax and abdomen were much distended. No caput madusa. Tongue coated; no temperature; pulse good. Some dyspnea. Liver and spleen could not be palpated on account of ascites. After some of the fluid had been withdrawn, liver was found slightly diminished in size, toward the median line. Spleen enlarged.

TREATMENT.

Patient put at rest, light diet, kidneys and bowels kept freely active. After a few days, paracentesis abdominis was performed, and two and one-half gallons of fluid withdrawn. Fluid soon returned and the patient was again tapped, and about two gallons of fluid withdrawn. Patient was doing nicely, but became dissatisfied and left the hospital about November 1st, against our advice. Patient returned to hospital November 20th, deeply jaundiced, ascites much increased. Oedema of feet, legs and scrotum had developed. The ascites was so great that it displaced the heart upward, apex beat being in fourth interspace. Marked dyspnea; pulse very rapid and weak.

TREATMENT.

Paracentesis abdominis was performed and about three gallons of fluid withdrawn. Eliminatives and supportive treatment again employed, and within twenty-four hours after tapping, there was a marked change of oedema of feet and legs, and most all being out of scrotum. Patient improved right along, and on December 19th was discharged from the hospital much improved. Omentopexy was advised but patient refused.

CASE II.

S. J., colored; age 39; admitted to hospital January 17th, 1912. Past medical history negative.

Personal History: Did not know whether he had had syphilis or not; most likely he had. Had been a steady drinker for about seventeen years; drank mostly a cheap grade of whiskey.

Present disease began four weeks previous to admission with dyspnea; abdomen began to swell gradually; later oedema of the feet developed. Patient much emaciated; had hepatic facies; apex heart displaced downward and outward; no enlarged superficial veins perceptible. Pulse rapid and weak; respiration rapid and jerky. There were moist rales over both lungs. Dullness over right apex; accentuated second aortic and pulmonary sounds. After fluid was removed, liver was found much decreased in size; spleen enlarged. Temperature ranged from 96.2 to 100.8; subnormal temperature in the morning. Patient never vomited or passed any blood by bowel. Sputum was examined twice for tuberculosis, with negative results.

TREATMENT.

Eliminative and supportive. Paracentesis abdominis was performed on January 23rd, and two and one-half gallons of fluid withdrawn. Patient showed very little improvement and died January 31st. No post-mortem was made.

DISCUSSION.

J. Rowan Morrison: I saw this man in the ward during my service at the City Hospital. He presented the ordinary type of cirrhotic liver, diminished in size, and had gone on to the stage of emaciation and ascites, and had lost a great deal of weight and strength.

The most important thing I noted in connection with this man was that, at the third tapping, three gallons of fluid were withdrawn. He had a colon very greatly distended with gas, causing considerable displacement of the heart upward. He was cyanotic and had oedema of the feet and scrotum, which was not of the hepatic type, but seemed to be due to interference with the heart, showing very beautifully what possibly occurs from displacement of the heart by gas. This almost led to a fatal result, because on the day the man was tapped he was in very bad condition, but upon removal of the fluid he promptly recovered from the symptoms referable to the heart. I think this distension of the colon with gas, displacing the heart and impeding the circulation, occurs in many instances, and is often the real cause of death from what is termed "acute indigestion."

There is still another interesting feature of this case. This man was tapped only three times, the last time in December, and improved considerably while he was in the hospital. Then he left the hospital and has resumed work. He does hard work, and he tells me that he has not

had very much return of the ascites. That is the history in many of these cases.

As to treatment, I think much can be accomplished by taking off the fluid in the proper way, using a medium size trocar; also, by the administration of iodid of potassium in small doses, over a considerable period of time. Dieulafoy says that he gives only three grains a day, but this should be kept up for a long time, a year or more, keeping the patient on a low diet and excluding alcohol if possible.

I advised omentopexy in this case. It will be recalled that on one occasion Dr. Grant exhibited to this society a patient in whom omentopexy seemed to have done a great deal of good. Upon looking up the subject it seems that the authorities are in doubt as to whether or not omentopexy is advisable, because in many instances where it has been done the patients did not get any more than the temporary relief which may be obtained from tapping, and the trouble soon returned. In many cases, however, they probably do get more and longer relief from omentopexy than can be obtained from repeated tapings.

W. C. Dugan: I do not believe this patient belongs to the class of cases in which omentopexy is advisable; it is in hypertrophic and not atrophic cirrhosis that the best results are obtained from this operation. The operation that I should think would offer the best results in atrophic cirrhosis of the liver, would be subcutaneous drainage, either by means of a glass tube placed in the peritoneal cavity (which it is claimed can now be done), or by lymphangioplasty as advocated by Sampson Handley, consisting of the introduction of silk threads intended to serve as artificial lymphatics, thus establishing drainage for the fluid, just as we establish drainage in hydrocephalus. I think this would be the operation in these cases rather than omentopexy.

Siegel C. Frankel: I saw this patient several times before he was tapped. At that time the oedema and ascites seemed to me to be due to cardiac trouble rather than the liver condition. He was oedematous all over the body, including legs, scrotum, etc., and had decided dyspnea. My prognosis at that time would have been very grave. This is the first time I have seen the man since then and I am rather surprised at the improvement that has taken place.

J. Garland Sherrill: I cannot agree with Dr. Dugan in the statement that omentopexy should not be done in atrophic cirrhosis. The object of the operation is to re-establish circulation and relieve the congestion resulting from the contraction of the liver. Therefore, in my opinion, it would be indicated in atrophic cirrhosis. I have performed omentopexy in only two cases in both of which there was improvement. One is still living and the other died later from a con-

tinuation of the cirrhosis. Recent reports along this line are rather more favorable. At a recent meeting of the Southern Surgical and Gynecological Association, Dr. Grant read a paper on this subject, and in the discussion which followed, the tendency was to advocate this operation in cases of cirrhosis.

Another method might be considered here. It has been proposed to unite the portal vein with the vena cava as a means of relieving the compressed vessels and carrying the blood back to the heart. This, however, is an operation which can only be undertaken by men who have had a good deal of experience with it experimentally.

J. Allen Kirk, (Closing): One thing that made me think this man's condition was not in any way connected with the heart was the fact that, after the third tapping, there was marked improvement in twenty-four hours. As a rule we do not see such prompt improvement in such conditions due to the heart.

INTRATHORACIC GOITER.

(REPORT OF CASE AND EXHIBITION OF SPECIMEN.)

By JNO. R. WATHEN, Louisville.

These three thyroid lobes were removed from a woman, Mrs. D., aged 35, who presented herself with symptoms of exophthalmic goiter, with a pulse of 140, eye symptoms, and besides the nervous condition, a decided sensation of choking or smothering on slight exertion.

The tumor, upon inspection, appeared as a mass about the size of a hen's egg, in the middle line and low down, just above the sternal notch; also an enlargement on the left side, high up.

At operation, when the goiter was exposed, the central mass was connected to, or continued as a large mass dipping down behind the sternum into the thorax. The lobe on the right side above the sternal notch was removed without difficulty, and when it was separated from its continuation into the chest, the latter part retracted deep down into the thorax. With much difficulty this was removed.

Intrathoracic goiters are of rare occurrence, and Mayo reports only 18 cases operated upon. Kocher says they are rare but does not give the relative figures. All agree that they are the most serious cases for operation and present problems hard to deal with. The tumor is delivered with much difficulty and should be enucleated rapidly, leaving the lowest portion attached to the capsule in order to bring this capsule up into the wound to obliterate the large cavity left below after the goiter is removed.

Mayo writes: "In our experience, great hemorrhage followed delivery of the goiter in all but one case. This hemorrhage was venous and was checked immediately by packing four large abdominal sponges within the chest, which were left in place four days, then removed without trouble, and a lighter pack substituted."

The patient from whom these specimens were removed has made an uneventful recovery and is now ready to leave the Infirmary.

DISCUSSION.

W. C. Dugan: I think the point the doctor made about leaving part of the tumor attached to the capsule is a very important one. If the capsule should be dissected loose and allowed to drop back into the chest it would be a very difficult matter to recover it and arrest the hemorrhage. Dealing with it as he did made the operation very much easier and enabled him to deal with the hemorrhage very much better than he could otherwise have done.

MEDICAL PROGRESS

DEPARTMENT OF OPHTHALMOLOGY AND OTOLARYNGOLOGY.

By GAYLORD C. HALL, Louisville.

AUTO-TOXAEMIA IN OPHTHALMIC SURGERY.

In a paper read before the American Academy of Ophthalmology, 1911, Dr. S. D. Risley discusses several features which make up a large proportion of complications and failures in this class of work. He calls attention in particular to the dangers of intestinal toxæmia, diseased nasal cavities and diseased teeth as responsible for the toxins which give rise to such diseases of the ciliary body and iris that serve as later complications in otherwise successfully performed operations, particularly in the operation for cataract.

Referring to the unsanitary condition in hospital patients as the probable cause of such diseases in the first place he says, "The impaired health, high tension pulse, the traces of albumin and the presence of indican in a urine of high specific gravity and a blood pressure often as high as 200 mm. of mercury are not promising conditions under which to undertake so serious an operation as the extraction of a hard cataract.

The attacks of iritis or irido-cyclitis occurring on the fifth to the seventh day, sometimes acute, more frequently painless, but attended by increasing redness, photophobia, tenderness of the ball and prolonged convalescence usually belong to this group of patients. There is a gluing of the iris to the capsule.

which becomes daily more tough and opaque; and even after successful secondaries there is impaired acuity of vision, due to infiltration of the vitreous or even to streamers of lymph stretching across the vitreous chamber. In bad cases, we are compelled to witness recurring hemorrhage into the anterior chamber, the steadily contracting pupil, which is drawn upward, and final failure to secure useful vision.

Their analogue in private practice is furnished by women after middle life who have passed through the stress of the social whirl; or by men worn to the breaking point by the anxieties and responsibilities of great business enterprises or by the physiologic vices inseparable from dissolute living.

What has been said regarding the history and essential nature of a large group of cataract patients is also true for the patients afflicted with inflammatory glaucoma. I have with many others, written so frequently of this as a local manifestation of cardio-vascular disease, that it seems unnecessary to dwell upon it in the brief time allotted to the presentation of papers. But increasing experience serves only to emphasize the gravity of this disease. In its worse phase, that of hemorrhagic glaucoma, we all know that its hopelessness grows out of the fact that the arterial disease is already so far advanced as to promise a speedily fatal result."

The conclusions are in accord with the investigations of DeSchweinitz regarding the production of choroiditis from absorption from the intestinal tract and it is interesting to note that at the same meeting Dr. Reber read a paper on the probable relation of uveitis to latent nasal obstruction in which he says, "There are a few very significant facts in relation to uveitis that are seldom touched on in the literature, namely: 1. It is a disease that seldom occurs in children.

"2. It is most frequent in young adults and fairly common in older subjects, especially those of advanced age, when it pursues a quite low form with a few spots on the posterior corneal surface and some vitreous opacities.

"3. It is more frequently monocular than binocular. Weeks is also of this opinion, and it is a fact that should give us pause; the more so as we have come to believe in a general way that many distinctly one-sided ocular affections are very much more likely to be of focal than general origin.

"4. There seems to be little tendency for the second eye to become involved.

"5. These forms of uveitis due to general constitutional disorders usually appear in both eyes at about the same time; and as a rule give rather frank evidence of the etiology of the ocular disease.

"6. The unilateral cases are commonly of very obscure origin unless one follows up the possible nasal or sinus origin of the trouble. In this event they are very likely to find that a seemingly idiopathic uveitis proves to be plainly of focal origin."

The work of these investigators serves to establish that there is an increasing tendency to go beyond the limits of the eye itself for the explanation and solution of a number of diseases which have heretofore been very difficult to deal with, particularly from the fact that we were not familiar with their etiology. This should therefore serve as a reminder to those of us engaged in special work that we should not attempt to restrict either our investigations or treatment within too narrow limits.

II.

COMMON COLDS.

Progressive Medicine, for March, 1912, reviews some very interesting observations in regard to common colds.

"Common Colds. An investigation of the prevalence of common colds and the economic loss due to them was made by James A. Honeij, and his results are very interesting. Fifteen thousand cards of investigation were sent out, and resulted in 1633 cases of colds fit for careful study, although the total number of individuals with colds was 3,845, or, including the persons in the family affected with colds, 6591. The summary is as follows: (1) Over half the population have colds during the course of the six months from December to June. (2) One-fifth of the population are absent from work on account of colds. (3) The average loss of time for 568 individuals was six days per six months. (4) The average loss of money was \$21.00 per six months, not including individual expenditures for medical treatment, etc. (5) The total loss in six months' time was \$12,105.37 for 568 individuals. (6) In addition to this there is a loss of energy equivalent to three dollars per six months per person. (7) The most common cold is the "head cold." (8) Most colds occur in the month of March. (9) Individuals from thirty to forty years of age suffer most from colds. Department store employees suffer most in proportion. Half of them lose time on account of colds. The conclusions drawn from this investigation are: (1) Preventive methods are essential in dealing with common colds. Better working conditions, pure air, even temperature, proper ventilation, and the proper amount of humidity are important factors. Nourishment, general hygiene, and proper clothing are necessary precautions as in guarding against all other diseases. (2) After the onset of a cold, proper diagnosis is essential to ascertain whether the

cold is infectious. (3) Individuals suffering from infectious colds should be isolated."

In the same journal an article by Macfie on Draughts and Colds states that while they play an auxiliary part in the production of colds they are easily deprived of the danger and should be favored rather than feared. He concludes "The man who endeavors to avoid cold by avoiding all draughts will not only catch more than his share of colds but will possess less than his share of health and vigor. Regarding the treatment, Hexamethylenamin has been recommended by several authorities but in doses which seem to the writer heavier than can be borne by the ordinary patient with comfort. Fifteen grains four times a day is recommended followed by copious water drinking to lessen the possibility of bladder irritation. The writer has seen five grains four times a day produce such irritation and feels that the dose should be adapted to the sensitiveness of the patient. This remedy is of undoubted benefit also in suppurative otitis media.

III.

SINUS DISEASES.

Investigation of the diseases of the various sinuses continues to invite discussion. There is now known two distinct kinds of ethmoidal diseases, one with the discharge of pus accompanied by polyp formation; the other a non-suppurative form. One of the most interesting symptoms of the sinus diseases are those relating to the eye. The researches of Onodi and Loeb have shown the intimate relationship that exists between the sphenoidal sinus, posterior ethmoidal cells and the optic nerve. It is therefore not surprising that suppuration within these cavities should give rise to ocular symptoms. The most common symptoms are the enlargement of the blind spot and central and paracentral scotomata. The eye is affected either directly through the bone, or by the blood, or lymph streams.

Kyle, writing in *Progressive Medicine*, classifies the optical signs and symptoms as follows:

"Frontal Sinusitis: Periostitis and orbital cellulitis, exophthalmos, diplopia, hyperemia of the optic disk, haziness of the vitreous.

"Maxillary Sinusitis: Blepharospasm, lachrymation, purulent dacryocystitis, edema of the retrobulbar tissue, exophthalmos, hyperemia of the optic disk, visual disturbance, transient amblyopia, amaurosis.

Ethmoiditis: Mucocoele, purulent dacryocystitis, diplopia, exophthalmos, amaurosis.

"Sphenoidal Sinusitis: Paralysis of the third nerve, of the sixth nerve, and of the second division of the fifth nerve; papillitis, retrobulbar neuritis, optic atrophy.

"The explanation of amblyopia and amaurosis is to be sought in the anatomical surroundings of the optic nerve while in the optic foramen, where pressure may be exerted on the nerve by distention of the veins surrounding it, or by sympathetic edema into the nerve and nerve sheath.

"Visual disturbance due to nasal disease is frequently unilateral, and though it is usual for the homolateral nerve to be affected, occasionally it is the contralateral alone.

"Chemosis, papilledema, proptosis, paralysis of the ocular muscles, and redness of the eye-lids form the important ocular signs of that very grave disease cavernous sinus thrombosis, often a result of suppuration in the sphenoidal sinus or in the posterior ethmoidal cell.

"Occasionally disease in a nasal accessory sinus, while giving rise to reflex symptoms, does not exhibit any very definite sign of its existence, so that attention not being directed to the origin of the mischief, it is at first apt to be overlooked."

IV.

ON THE NATURE, CAUSE AND RELIEF OF GLAUCOMA.

Under the above title Martin H. Fischer read a paper before the American Academy of Ophthalmology. He shows that experimental glaucoma can be produced in an eye in the entire absence of any circulation and says, "We are at the same time led to conclude that the cause of glaucoma may well reside in the tissues of the eye itself, and that it becomes glaucomatous not because fluid is pressed into it, but because through changes in it, it absorbs an increased amount of water. Our experiments further show that this increased absorption of water by the eye is dependent upon the colloids in the eye, for not only is the eye built up of a series of different colloids (sclera, cornea, lens, vitreous humor), but the same conditions which govern the absorption of water by fibrin also govern the absorption of water by the eye. On the ground of these experiments we can, therefore, no longer insist that an eye becomes glaucomatous because water is forced into it. It does this because chemical changes occur within the eye which increase the affinity of the ocular colloids for water so that these are enabled to absorb water from any available source. In the experiments with enucleated eyes this source is the solution into which the eye has been dropped; in the body it is the liquids flowing about or through the eye."

Regarding the relief for such conditions he says, "Our results may be summed up as follows:

"The use of subconjunctival injections of

a one-eighth to one-sixth molecular (4.05 to 5.41 per cent. solution of chemically pure sodium citrate in clinical cases of glaucoma is entirely harmless and is always followed by a prompt fall in ocular tension. The fall in tension is appreciable within ten minutes after the injection and may be so great as to make the eye have a subnormal tension. The effect of such a subconjunctival injection lasts for from three to six days (or even more) and is accompanied by a relief of all the subjective symptoms of glaucoma (except, of course, the blindness due to structural changes).

"It must be clearly understood that when such subconjunctival sodium citrate solutions bring about a diminution in the tension of a glaucomatous eye, this does not constitute a 'cure' for glaucoma. As a cure of glaucoma we could only consider a removal of that condition or conditions which are responsible for the development of the substances which increase the affinity of the ocular colloids for water.

"Writers on ophthalmology are in the habit of laying great stress on the obliteration of the filtration angle. This is frequently said to be the cause of glaucoma. It is much more probably a consequence as evidenced by the fact that enucleated eyes rendered artificially glaucomatous by being placed in acid solutions show the same progressive decreases in the depth of the anterior chamber that is noted in clinical cases."

"Under systemic treatment he says, "It is not enough, after having reduced the tension in a glaucomatous eye by the subconjunctival injections of sodium citrate to let the matter rest. Every effort must be made to discover the various factors that are responsible for the chemical changes (acid production) that lead to the increased swelling of the ocular colloids."

The article should be read in its entirety.

COUNTY SOCIETY REPORTS

Barren—The Barren County Medical Society met in regular session in Glasgow, April 9th, 1912, with the following members in attendance: Jordan, Leech, Britt, Smock, Plumlee, Ferguson, Turner, Botts, Taylor, Froedge, Honaker, Siddens, Miller and Porter.

Order was called by President Smock, who expressed the pleasure it gave him to see so many genial faces after the long cold winter and late muddy spring.

The minutes of last meeting were read and approved.

Jno. W. Acton was received by card of transfer from the Lincoln County Medical Society.

The society next considered the application for membership of Dr. Christopher T. Grinstead pre-

sented last meeting. Motion unanimously carried that he be admitted to membership.

Clinical cases and reports were called for.

S. J. Smock presented a child three years old, who for the last year has suffered from what he considers epileptoid attacks coming on at irregular intervals, being accompanied by tonic contraction of the muscles of the back and upper extremities. The seizures are accompanied by some mental confusion, though consciousness and memory are retained. There are large purple spots over the cheeks, otherwise nothing notable in the child's appearance. The case was discussed by several members, but no diagnosis was agreed on. Calomel and Santonine were advised.

J. S. Leech related some of his recent experience with rheumatism, which was followed by a general discussion of this troublesome disease, many interesting points being brought out.

J. C. Jordan gave a short talk on our Vital Statistics law. The discussion which followed indicated that the law is not popular with the laity, though approved by the medical profession of this county.

Motion carried that our annual social meeting be held here on Tuesday, July 9th, and that a committee be appointed to make suitable arrangements for same, and report at next meeting. T. F. Miller, R. H. Porter and J. M. Taylor composed said committee.

Following is the program for our next meeting:

1. Clinics and reports of cases.
2. Paper on "Constipation" by W. T. Britt; discussion by Acton and others.
3. Paper on "Hic-Colitis," by A. T. Botts; Miller to lead in a general discussion.

Adjourned to meet in Glasgow, May 14th, 1912, at 10 o'clock a. m.

J. M. TAYLOR, Secretary.

Bell—The Bell County Medical Society met in Middlesboro, April 12th, at the office of C. K. Broshear, with President J. Harry Henderson presiding. The following members responded to the roll call: Drs. Hendren, Evans, Haston, Foley, Wilson, Nickols, Schultz, Coombs, Giammi, Clayton, Chance, Edmonds, Robertson, Gibson and Tinsley.

The minutes of the previous meeting were read and approved.

The committee appointed to confer with the fiscal court, reported favorable progress, and thought the prospect good for a nice appropriation for the purpose of furthering sanitary work in the county, but asked for further time for a final report.

C. F. Clayton presented a very interesting clinic, which was regarded by most of those who discussed it as one of the forms of eczema.

C. K. Broshear was compelled to be absent from the meeting, but had an interesting clinical case presented by **L. L. Robertson**. It was conceded to

be a case of urethral chancre in patient 65 years of age.

T. T. Gibson asked for reciprocity with Virginia, for the purpose of doing some special work just across the Kentucky and Virginia line, which was cheerfully granted.

Mason Coombs presented the application of H. G. Petrie for membership, which was referred to the board of censors.

It was moved and seconded that the chair appoint a committee to prepare a program, and special meeting for next month, with power to prepare luncheon at the expense of the society. Drs. Foley, Robertson, Schmitz and Nuckols were appointed, with chairman Hendren *ex officio* member.

Edward Wilson read a paper on "Eclampsia" which was very timely.

Mason Coombs gave a practical paper on "Clinical Microscopy." Both papers were much enjoyed by the members of the society.

There being no further business the society adjourned to meet in Pineville, May 10th, 1912.

O. P. NUCKOLS, Secretary.

Harlan—On April 10th, Dr. J. S. Loeck, Conncilor for this district, was with us and gave a very instructive and entertaining lecture in the court house, at Harlan, to a large and appreciative audience, his subject being "Hookworm," at the close of which he organized the Harlan County Medical Society with the following doctors present: G. P. Bailey, W. S. Howard, J. L. Bieroch, Wm. Martin, W. P. Coward and Arthur Jenkins. The following officers were elected: President, G. P. Bailey; Vice President, J. L. Bieroch; Secretary-Treasurer, Arthur Jenkins. Meetings are to be held on the first Tuesday of each month.

ARTHUR JENKINS, Secretary.

Russell—The Russell County Medical Society met at Jamesdown at the Holt Hotel, on the 20th of April, 1912, with the following members present: L. D. Hammond, Scholl, Flanagan, Rowe, Trater, and Blair. The meeting was called to order by President L. D. Hammond. Minutes of the previous meeting were read and approved.

On motion and second J. S. Rowe was elected Censor for the present year, instead of J. D. Combest.

J. B. Tarter and J. M. Blair were appointed a Committee on Program for the next meeting, to be held at Salem Church, in Russell county, on the first Saturday in June, 1912.

J. M. BLAIR, Secretary.

Bourbon—The Bourbon County Medical Society held its regular monthly meeting in the county court room of the Bourbon county court house, Thursday, April 25th, 1912, at 8 p. m.

The following program was carried out:

Reading of minutes of preceding meeting.

Reports of committees including Hospital Committee.

Report of clinical cases:

C. G. Daugherty reported a case of "Facial Erysipelas."

Frank Fithian, reported a case of "Delayed Chloroform Poisoning in Obstetrics." Three cases.

W. McKeeney read a paper on "Muscular Rheumatism."

W. G. Dally read a paper on "Inflammatory Rheumatism."

General discussion.

Presentation and discussion of amendment, "To organize the Bourbon County Medical Society, meeting monthly and to change County Society to quarterly meetings, a regular dinner being served."

This was an important meeting, and a full attendance was had.

D. B. ANDERSON, Secretary.

C. G. DAUGHERTY, Assistant Secretary.

Eversion of the Tunica Vaginalis in Treatment of Hydrocele.—Cernezzi has applied the Longuet technique for extraneous transposition of the testicle in nineteen cases since 1903, bilateral in three, with prompt and permanent relief. He emphasizes the necessity for making the incision over the upper pole of the tumor as thus the lips of the serosa can unite better afterward and form the sheath for the cord. Also that a silk suture before the catgut suture holds the parts in place better. He also warns against the slightest unnecessary orision of the testicle, and adds that it is unnecessary to drain.

Graphic Signs in Pulmonary Work.—The Journal has published articles on the subject of using signs or hieroglyphics to represent the auscultation and percussion findings, "clinical shorthand records." Nahm here gives the chart and signs which he has found most convenient for the purpose. (Harach's signs, based on the phonetic values, were illustrated in the American Medical Journal, Nov. 6, 1909, page 1541; they are widely used.

Turbidimetric Tests of Milk, Blood and Other Fluids.—The fluid in a very tapering wedge-shaped vial or glass is inspected through a narrow slit. As this slit is moved upward a point is reached where objects behind become visible through the fluid which is more or less opaque at the thick end of the wedge vessel. Schlesinger says that one is able thus to estimate the fat content of breast milk and market milk and detect admixture of water, to estimate the number of corpuscles in the blood, and, after restriction of the red corpuscles, to determine the proportion of whites.

EDITORIAL

A. M. A.

The approaching meeting of the American Medical Association, at Atlantic City, promises to be the most valuable and interesting one that it has ever held. The program is replete with good things and it is hoped that at least 250 Kentucky doctors will take advantage of this opportunity for a practical post-graduate course. Arrangements have been made for a special train leaving Louisville over the Pennsylvania lines, on Sunday, June 2nd, at 1:10 P. M. This train will run through into Atlantic City without change. If you are going, write at once to C. H. Haggerty, Fourth and Market Streets, Louisville Kentucky, and reserve sleeper accommodations. Members from the Eastern part of the State can catch the train at Cincinnati, at about 4 P. M. on the same day. Ask your ticket agent for a thirty-day, summer tourist fare ticket to Atlantic City and return. This will cost \$29.00 from Louisville.

This will be a specially nice trip for the doctors' wives and children. Hotel accommodations at Atlantic City are abundant and can be secured at any price from \$1.00 a day up. It is a great opportunity for us all to see the ocean.

The return trip may be made via Washington, and ticket holders will have the privilege of stopping over at Cincinnati, Columbus, Ohio, Pittsburgh, Baltimore, Washington, or Philadelphia. A special post-graduate course will be offered to those attending the meeting in Philadelphia, free of cost, following immediately upon the close of the meeting.

PAYMENT OF FEES, UNDER VITAL STATISTICS LAW.

One of the greatest tasks the office force of the Bureau of Vital Statistics has had to perform since its existence, was the issuing of vouchers to physicians, local registrars and midwives. About ninety-six hundred of these had to be written, checked with certificates from each county and made to total individually and collectively with the certifications of the State Registrar, sent to one hundred and nineteen counties of the State. A force of ten clerks worked entirely upon this task for nine weeks and many times were compelled to work at night.

A great deal of the difficulty lay in the fact that many certificates were incomplete or delayed in registering, and these had to be gone over carefully before credits could be given under the law. If the physicians this year will review and complete each individual certificate, giving names, dates, ages, cause of death, and all the information necessary for statistics worthy of the name, it is expected that vouchers may be issued next year within thirty days after the receipt of the last certificates.

The voucher is complete in itself, being a check on the county treasurer, who by law is required to pay these claims, upon certification by the State Registrar, a receipt for the county and an itemized statement of account.

A number of progressive counties have already paid these claims, Ohio, Jefferson, Fayette, and Warren among them. Jefferson county having the largest population, naturally had the largest claim, \$4,800.25. Dr. Heizer, State Registrar, appeared before the Fiscal Court of that county, explained the working and intent of the law, and the bene-

fits to the citizens of the county and State, in keeping permanent family records, and the advantage such records have in enabling the State Board of Health to locate epidemics and through the cooperation of the people and health officers, be able to save many lives and much suffering. A practical application of such use being found in the control of the epidemic of cerebro-spinal meningitis in Louisville of this year. The State Registrar issued instructions that all burial permits for persons dying from that disease, must be issued from the city health office, thus insuring that all cases resulting in death should come to the knowledge of the proper health authorities. That Court unanimously voted the appropriation, after an opinion by Hon. Scott Bullitt, County Attorney, upon request of County Judge Weissinger. Mr. Bullitt agreed with State Attorney General Garnett, and the courts of last resort in many other states which have this law and its identical provisions for the payment of fees, that upon certification by the State Registrar of the amounts due physicians, local registrars and midwives, such amounts shall be paid by the treasurer of the county, and in order to safeguard the county's finances, and comply with the usual regulations in paying county funds, the Fiscal Court should pass upon these claims and allow them as other claims against the county are paid.

After this year, when, of course, the payment of these fees would cause some comment, there need be no further delay in securing the payment of such vouchers, and it is hoped that all certificates of births and deaths will be completed and registered promptly, so that a quicker delivery of these checks may be made.

Our results last year broke the record of registration in the United States, and Kentucky doctors are too well known for their ability in "delivering the goods" to expect less this year, when the hardest part of the road has been traveled.

A GOOD PHYSICIAN DESCRIBED.

Our attention has been called to a rather remarkable sermon, recently delivered by the Rev. C. A. Owens, of DeLand, Florida. The following are fragments from the sermon:

"It is one of the most important and oldest of the professions, dating back 3500 years before Christ.

"If a doctor would succeed in his profession, he should let other businesses alone. I do not want a physician to wait on me who has other distracting matters on his mind, who has so many irons in the fire that he

subordinates unconsciously perhaps his medical practice to other matters.

"Having temptations for evil and opportunities for good, more numerous than any other profession, medicine has some of the noblest and some of the best men in the world in its ranks. Above all others he most requires the grace of God.

"We want him to be trained, with a good college course, and four or more years as required to get his medical diploma to practice. The profession itself is so regardless of its integrity as to provide the strictest examinations before skilled critics of the profession, so that more and more we see the safeguards to our lives and health being erected by the profession itself, to whom we should be grateful for these protective measures.

"As a rule we should not put our patient knowledge above the diagnosis of our faithful family physician, nor should we patronize or favor the foreign physician, who can have no such vital interest in our lives as has our home doctor.

"Jealousy among physicians is a curse, it almost universal defect—

"Trifles light as air, are to the jealous heart, proofs strong as evidence of Robt. Writ."

"There is a need of friendlier feeling among them, as the public is apt to adopt the estimate they put upon each other, since a man rarely pays a higher price than the marks on his product.

"Our debts to our doctors are sacred. Through snow and rain and heat and cold they come to your stricken couch, themselves hungry, thirsty and weary, to save you from providential afflictions or from the results of your own imprudence or rashness—therefore, pay them what you owe them!

"No profession does so much charity work as the doctor, and none has so many uncollectible accounts. Few ever refuse to wait on the sick at any time, while in pestilence, or in sudden calamities the physicians form a noble volunteer army against death and disease.

"The time is coming when, instead of charging for treating the sick, physicians will be in China where they are salaried to keep individuals well! And when they fall ill, the doctor must treat them free!

"Let the doctors be clean in mind, in person, in speech, and have no pleasure in the counsels of the wicked and ungodly. Let him never betray the family secrets lodged in his breast by trusting patrons. For such violations, he should be put in stripes.

"The physician should stand in the front ranks in moral reforms against the social sin."

intemperance, and the enemies of the public health.

"Pray for your physicians, subject as he is to attacks of physical and moral sickness, tempted as perhaps no other man is tempted."

"In your infancy, in your manhood and at your death bed he is beside you, patient, tender, sympathetic, faithful. As Luke was called the Beloved Physician, and the Great Physician, let their earthly prototypes ever remember their high and noble calling."

It is important that the qualifications of the various professions and avocations of life be publicly discussed, especially, from the pulpit. It is a pleasure to congratulate this Florida minister upon the discretion and skill with which he has undertaken this task.

PIN WORMS.

In reply to a request from the State Board of Health, Dr. C. W. Stiles, the distinguished Zoologist of the Marine-Hospital Service, has written the following regarding pinworms: It is printed here because of its general interest to the profession of Kentucky.

"The young pinworms live in the small intestines and the males and females mate in that region. The fertilized females withdraw to the cocoon and later when gravid to the colon.

TREATMENT

"Treatment should take into consideration two distinct points; namely, not only the removal of the gravid female pinworms from the rectum, but also the removal of the younger worms from the small intestine. A failure to consider this latter point doubtless explains not a few cases of treatment which have not met with the success the practitioner expected. Still, the emphatic statement so often met with, that persistence is an essential factor in favorable results, is often justified.

"For removing the younger pinworms from the small intestine, several drugs may be used, as *santonin* and *calomel* (of each 0.05 to 0.1 gm.—3-4 to 1 1-2 grains) given several days in succession, or large potions of an infusion of *gentian*, or active saline cathartics repeated several days in succession, or *thymol* or *beta-naphthol*. *Ungar* gives immediately after a laxative, four doses per day of *naphthol* (0.1 to 0.4 grams—2 to 6 grains) according to age, for two or three days in succession between meals.

"To expel the gravid females from the rectum, rectal injections are used. An infusion of *quassia* seems to be one of the most popular remedies. Other commonly used enemata are: lime-water, aloes, diluted vinegar (which should be sterilized before using, otherwise the patient may become infected

with vinegar-ells), perchloride of iron, glycerine, benzine, (20 drops to a pint of warm water), finally chopped garlic with water (which has stood for twelve hours and is then strained through linen). Diluted carbolic enemata are advised by a number of authors, but they do not seem to have any special advantage over the other drugs and have in some cases decidedly poisonous effects.

"The injections are given with the buttocks elevated, or in the knee-chest position, at first every evening, then every two or three or four evenings, until all evidence of worms has disappeared. If too large an injection is given to be retained this washes out a number of worms; but it should be followed by a smaller injection, two to four ounces, or an amount which can be conveniently held.

"Ointments of various kinds may be applied in the evenings to the anus and perineum to relieve the itching."

MEDICAL MILK COMMISSION.

The Sixth Annual Meeting of the American Association Medical Milk Commission was held at the Seelbach Hotel Louisville, on April 30th and May 1st. There were twenty-seven out of sixty-six commissions represented by delegates and included members from California on the West, New York, and New Jersey on the East, Canada and Minnesota on the North and Alabama on the South.

The papers and discussions were replete with interest. Perhaps the most important work which was done was the adoption of final standards of working methods for all commissions. Unfortunately all states have not safeguarded the use of the term Certified Milk to the Medical Milk Commission appointed by a regular medical society and milk is sold as Certified Milk which bears the seal only of a private and usually paid milk commission. The standards adopted are the ideals to which all commissions must work to bring Certified Milk to what it really should be. The following is a definition of what is meant by Certified Milk and which should carry with it an endorsement of a perfectly safe clean milk for use of infants and invalids.

"Certified milk is a product of dairies operated under the direction of a medical milk commission; which body is appointed for voluntary service by a medical society. The milk is designed to fulfill standards of quality, purity and safety to insure its adaptability for clinical purposes and the feeding of infants.

"The certificate of the commission constitutes its authorization for the use of the term 'Certified'. The certification is based on the fulfillment of prescribed medical requirements

for the milk and is the guarantee that it conforms to definite standards and to fixed methods and regulations for its production.

"The standards of quality consist of fresh, whole milk, unchanged by heat or cold, less than twenty-four hours old when sold, held between the temperatures of 48 and 50 F., with not less than 12 per cent. of total solids, with fat contents between 3.5 and 5.5 per cent. and without the addition of any other material, substance, chemical or preservative.

"The standards of purity for the milk consist of the entire absence of particles of foreign matter, of the lowest possible bacterial and dust-dropping content consistent with the highest possible practice of dairy hygiene, provided that the numerical bacterial contamination is at all times below an average weekly count of 10,000 per cubic centimeter.

"The standards of safety consist in the use of every known means to exclude from the milk pathologic microorganisms, a medical guarantee that every employee handling the milk is free from disease and is not a disease carrier, and a veterinary guarantee that the cattle are in perfect health and cannot transmit through the milk any bovine affection.

"The methods and regulations for the production of Certified milk are those adopted from time to time by the American Association of Medical Milk Commissions; they are based on the most advanced clinical requirements, prophylactic science and dairy husbandry, and are changed as the action of the association modifies its technic for the attainment of its standards."

There is no question, but that Certified milk is one of the best methods of conservation and prevention of infant mortality.

California has enough commissions in operation to form a state association of Medical Milk Commissions and we trust that it may not be long before Kentucky may have more than two as at present there is one in Louisville and one in Lexington for Certified Milk.

The Standards and Working Methods will be printed as a special bulletin by the Public Health and Marine Hospital Service as the final report of the Committee of which Dr. John W. Kerr, Assistant Surgeon General was Chairman. This Committee prepared and circulated a questionnaire to all commissions and as a result of the reports sent in the standards and working methods were formulated.

HENRY ENOS TULEY.

WHY WE SHOULD FEAR BUGS.

The feeling of instinctive revulsion against parasites of all kinds which characterizes humanity generally, and which is due to something much more than the mere pain or an-

noyance that their bites might inflict, becomes more interesting as further discoveries show the role of such insects in the spread of disease. Unfortunately this natural abhorrence has not been enough to protect man under conditions of poverty and uncleanness from harboring such parasites, and now those who understand how much more than a mere personal annoyance is in question from the existence of parasites must take up the problem of eradicating them. The possibility of the bedbug conveying relapsing fever, typhoid and leprosy,—has been suggested and apparently there is no parasite of man that may not be a mode of disease conveyance. Flies, fleas, mosquitoes and bugs—not only are all under suspicion, but most of them are also actually demonstrated as ordinary and frequent conveyors of diseases of various kinds. According to *The Journal of the American Medical Association* health authorities must now take up the problem of getting rid of insect parasites in order to stamp out disease.

ANTISEPTIC MOUTH WASHES CONDEMNED.

In commenting on the hundred and one proprietary antiseptics which are on the market and which are all based on the familiar alkaline Dobell solution the *Journal A. M. A.*, (April 13, 1912, p. 1137) gives the following opinion as to the value of antiseptic mouth washes:

"For the treatment of the mouth an alkaline solution is very useful for the purpose of dissolving mucus and thus mechanically removing much of the fermenting mass, which consists frequently of food particles enclosed in a tenacious mucus. The introduction of numerous ingredients into these mixtures for the purpose of giving them a pleasant taste or with the claim of rendering them antiseptic has led to a considerable degree of confusion and mystification in the mind of the practitioner, a condition of which the nostrum maker has been prompt to take advantage. It is time to call a halt in the making of these mixtures which exemplify the tendency to polypharmacy and to ask ourselves what is the object of such a confusing association of ingredients.

"It may be questioned, in the first place, what need there is of antiseptics in a mouth wash. The antiseptic action is of value only where the antiseptic is to act for some time on the mucous membrane or the contents of a cavity. A mouth wash is used for the temporary cleansing of the mouth and it is not to be supposed that its antiseptic ingredients will remain in the mouth in an efficient concentration for any length of time, and this limits its value."

We are inclined to believe that, except so far as they promote cleanliness, that mouth washes in general are of little value and it is time that not only the profession but the public are apprised of the general worthlessness of the complex antiseptic solutions that flood the market.

SHORT AND EASY ROAD TO WEALTH.

Would you like to sell a 15 cent product for \$4.50? Do you want to make money easily and quickly? Then take some ordinary food product (like cottage cheese) and give it some imposing name (like Sanatogen) and sell it for thirty times what it is worth. The public will buy it if it is advertised under some mysterious name, with profound scientific claims as to its value. This is the moral which *The Journal of the American Medical Association* draws from its investigation of Sanatogen. This product, which has been advertised widely in the newspapers and magazines of the United States and Europe, has practically the same chemical composition as cottage cheese being composed of from 83 to 95 per cent. of casein. According to its promoters and the people who furnish the testimonials, it is "a recreator of lost health," "a specific nerve tonic," "a scientific compound," containing "over 700 per cent. more tissue building, life sustaining nourishment than wheat flour." According to the chemists of the American Medical Association it is nine-tenths casein or cheese (and very expensive casein at that) with the addition of about 5 per cent. of glycerophosphate. A table compiled from Professor Atwater's calculation shows its relative value as a food and its cost as compared to other food articles.

King of Food Material	Price Per Pound	Cost of 1,000 Calories Energy	Caloric Energy for One Dollar
Sanatogen	\$4.54	83.01	532
Cheese	.75	.77	1,300
Eggs (\$0.26 per doz.) . .	.24	.30	2,000
Beef, round	.14	.16	6,300
Milk (\$0.07 per qt.) . . .	.075	.11	8,500
Pork, loin roast	.12	.10	10,200
Butter	.20	.08	11,250
Mackerel, salt dressed . .	.10	.05	20,000
Cheese	.16	.08	13,500
Beef, stew meat	.05	.07	15,300
Wheat bread	.08	.05	17,250
Rice	.08	.05	20,250
Sugar	.06	.03	20,250
Pork, fat salt	.09	.02	20,250
Potatoes	.01	.03	20,500
Beans, white	.05	.03	20,400
Catmeal	.02	.02	5,000
Cornmeal	.025	.02	6,400
Wheat flour	.025	.02	6,400

Like all "patent medicines," Sanatogen has been exploited by means of testimonials and printer's ink. Actors, authors, politicians and not a few physicians—chiefly European—have testified to the wondrous prop-

erties of this product. *The Journal*, besides the chemist's analysis, submits letters from eight of the leading American authorities in medicine, physiology and chemistry. Dr. L. F. Barker, professor of medicine of Johns Hopkins University, says: "All of its (Sanatogen's) good effects . . . can be got by including milk and eggs in the food." Dr. Frank Billings, professor of medicine of the University of Chicago, says: "The thing is a fraud both as a food and as a tonic." Dr. Richard C. Cabot, professor of medicine, Harvard Medical School, says: "It is vastly improbable that it has the properties claimed for it in the advertisements." Prof. Otto Folin of Harvard Medical School says: "For myself . . . I prefer a glass of milk." Dr. Ludvig Hekton, professor of pathology, University of Chicago, says: "The statements made in the advertisements are extravagant, misleading and quackish." Other equally eminent authorities agree with those quoted. *The Journal* concludes:

Herr Tenfeldtsdröckh was right when he panegyrized clothes. And the worship of clothes is carried to the extreme nowhere so much as in the case of word-clothes. The most plebeian of things when bedecked in sufficiently imposing word-finery are endowed with the attributes of royalty before which the average intellect bows down. Neither cottage-cheese nor glycerophosphates, when exposed naked to the world, command any overwhelming respect; combined and dressed in the magic word "Sanatogen," they receive the homage of those whose judgment is blinded by the glittering trappings of word-finery. Some day, possibly, there will be a democracy of intellect which will refuse to prostrate itself before mere word-raiment and will insist on appraising things at their naked worth. When that day comes, proprietary humbugs like Sanatogen will have become us extinct as the dodo and the great auk.

THE ADMINISTRATION OF TINCTURE OF IRON.

H. A. Sharpe, Mount Vernon, Wis., gives a very simple method whereby tincture of iron may be administered in such a way that the peculiar astringent effects of ferric chloride may be exerted in the stomach and yet without the danger of effecting the patient's teeth. The method consists simply in directing the patient to transfer by means of a dropper the required amount of tincture of ferric chloride to the lower part of an empty gelatin capsule. The cap is filled with water, the water then poured out and placed over the larger portion containing the ferric chloride. This capsule can then be swallowed without any danger of the iron coming in contact with the

teeth. The same method of administration is recommended for terebene, creosote, etc.—(*Jour. A. M. A.*, April 20, 1912, p. 1221.)

HOOKWORM.

A letter was addressed to every member of the Kentucky State Medical Association except those in the large cities, asking for their immediate co-operation in securing specimens from anaemic children, for the purpose of getting a fairly rapid but accurate survey of the infection from intestinal parasites in Kentucky. The response has been so complete as to be a surprise to everyone connected with health work. The Bacteriological Laboratory of the State Board of Health has supplied itself with 1000 mailing cases, with the idea that they would receive not more than this many requests for them. This supply was exhausted within a week after the letter was sent out and they are now returned to the laboratory, at the rate of from five to fifteen daily.

This is but another of the practical examples of the value of medical organization to the health and lives of the people. Bulletins telling all that is known about Hookworm disease have been mailed to every physician in the State and additional copies will be mailed upon request. This cooperative work and the diagnosis and treatment of this disease is one of the most important undertakings in which the medical profession has yet interested itself. When a doctor is in doubt about the diagnosis of a chronic disease, he should send a specimen of feces to the State Bacteriologist for examination.

SCIENTIFIC EDITORIALS.

TO WASH OR NOT TO WASH, THAT IS THE QUESTION?

• Every now and then a new apostle arises and raises his voice in the wilderness for the benefit and protection of the vast army of the unwashed. The last individual to be possessed of prophetic vision, is a British authority, so called, Sir Almroth E. Wright, who believes that too much bathing is unhealthy. We read with much surprise from an editorial in the *Literary Digest* that this individual remarks "I do not think cleanliness is to be recommended as a hygienic method," to which the comment is added that "these are not the words of an eminent Pinte Medicine Man, but a British authority on hygiene." This eminent scientist, author of a system of inoculation against typhoid and other bacterial vaccinations, said in a recent lecture on "*Bacteriology and Health*," "people say you must have hard exercise and a certain amount of washing and

a certain amount of fresh air, but I am persuaded that these rules are quite wrong. There is a belief that by washing, people wash off the microbes. We do take off a certain amount of microbes, but we also destroy the protective skin, which is all around our bodies, like the tiles of a house. When one has a horn hand, no microbes can ever get near the skin. A great deal of washing, increases the microbes of the skin, so I do not think cleanliness is to be recommended as a hygienic method."

The great work that Wright has done, in his study of opsonins, makes him an authority to be respected, but *only* in his own branch: which perhaps shows the folly of talking about something one is not thoroughly acquainted with.

The whole question does not commence and end with the bacterial content of the skin. The skin is an excretory organ, and discharges effete material constantly, upon its surface. This material is only partly soluble in water; a great deal of it is oleaginous in character: being somewhat sticky in character it catches a great deal of the impalpable dust and dirt of the atmosphere, even though we wear clothes. It may be remarked that the external layers of the epidermis are constantly dying, we all know, from personal experience what dead protein material will do, based upon our early experience with the disintegration of poor "Towser's" remains. In similar and lesser degree, putrefactive changes take place on the surface of the skin, and thus we have many things to consider besides the bacterial question. Perhaps Wright has been a little myopic.

The writer has very clear, definite beliefs with regard to this question. Mere bathing with water is not sufficient; the modern life requires, in our present civilization, the use of a cheap and useful article, to-wit; *soap*. Soap is an alkali; it mucratizes dead epidermis, loosens dirt and saponifies the fatty glandular discharges. Water and soap thus remove the dirt, the soluble material and the saponified mass from the skin, leaving it smooth and with its millions of pores open.

Now, I will grant, there is a world of difference between bathing and the British "Morning Plunge." The cold plunge bath is in the opinion of the writer the most trying method, for the application of cold water to the cutaneous surface, and should only be used when one is strong, has a good reactive power and has been gradually trained to the bath. Again I remark, as I have so often said in my writings and in my work "*Practical Hydrotherapy*," that a family would be far better off as far as health, vigor and feeling is concerned, if they would purchase a shower

bath and install it in a good bath room, than if they purchase some handsome ornamental hat rack for the front hall. I believe that small children should commence to bathe and keep up the habit until the "grim reaper" carries them from off this terrestrial sphere. Probably no single treatment in all the range of therapeutics offers such opportunities as hydrotherapy, and Wright, whose name carries great influence with it, has certainly been either misquoted or is in grave and deadly error. A warm bath, with soap, followed by a rinsing in warm water, then a *short cold* or *very short cold shower*, lasting only a few seconds, followed by vigorous friction with a crash towel, is a prescription that will in its practical application nullify the theory that this distinguished Britisher might entertain. It strengthens the cutaneous circulation, leads the great body of blood to the surface, strengthens the action of the heart, and prevents congestion of internal organs. The impact of the cold increases oxygen consumption, betters appetite, favors elimination and brings about wide changes in metabolism, such as are caused by no other agent. It will make one brighter, happier, and render their systems vigorous to resist some of the dangers that this bacteriologist would have us believe arises from the skin. His view is an absurd one, but as Hapgood remarks in a tiny editorial in Collier's "it may at least help some readers to learn that it was John Wesley, in a sermon "On Dress" and not some personage in scripture who placed cleanliness next to Godliness." In conclusion we might add that the bath here suggested is not an offense against healthfulness in any sense of the word. We have refrained from mentioning the disagreeable features that might be the fate to those who would be so unfortunate as to have to be thrown with the unwashed in close and daily contact. It would indeed be a strain upon their olfactory nerves. Let us hope that the modern is in the ranks of the gamin and a "little too wise" to accept even so eminent an authority as Sir A. E. Wright, even if there is in everyone a certain reverential feeling for authority.

CURRAN POPE.

HOW SHALL WE DIE?

"Can storied urn, or animated bust,
Back to its mansion call the fleeting breath,
Can Honor's voice provoke the silent dust,
Or flattery soothe the cold, dull ear of
death?"

—(Gray's "Elegy in a Country Church-yard.")

Perhaps nothing since the Iroquois Theatre fire has stirred the emotions of the American people to such an extent as the deplorable

wreck of the Titanic, a gallant craft of enormous size, equipped with every modern luxury, destined to be a great greyhound of the Atlantic, a model that went to make up the sum total of man's knowledge of sea travel. Leaving her port of departure, she turned her head toward the West, as staunch a ship as ever pressed its proud prow and keel against the turbulent waters of Father Ocean. Titanic in name, Titanic in size, with all the pride of pomp and power, in the glory of her maidenhood, she raced to a doom, the awful tidings of which have brought despair to homes and stunned the faculties of sympathetic humans. The story has been told, and man taught that after all, he is but the atom that his Creator made him; that he has been humbled by a frightful and fearful lesson; that, that which is made by man's hands is frail and uncertain, and only that made by Deity, lasts with the indestructableness of the granite hills.

Man, in his proud boastfulness has been taught this sad and serious lesson; has been shown that the modern *speed mania* is a menace to life; the curse to civilization, which can be truthfully said to travel on land, as well as on sea. With panting, throbbing, pulsating engines, the great Titanic responding like a noble and blue-blooded race horse to the touch of the master's hand, plunged forward with ever and ever increasing speed, only to become a victim of a national mania, that is fast reaching the proportions of a *national neurosis*.

Death sat gaily on the prow, taking his toll of many lives, lives that are precious, lives that are useful, lives that mean happiness, comfort and support to others, but death was not alone. Chivalry and Gallantry, hand in hand, stood side by side on that deck where heroes died. One may "Be British," but after all, this is but the expression of an Anglo-Saxon trait. These men were men, and it will be a long time before "we shall look upon their like again."

Out of tragedy, out of sorrow, out of travail and suffering, good invariably springs, and human though the reflection may be. Disaster is stern teacher, but like experience, it is a sure one, and out of this holocaust it is to be hoped that rules and regulations will be secured that will prevent a like disaster.

There were physicians on board; some were saved, some died. They were doctors, but first of all they were men and they met their fate unheralded and unsung, but we at least in the profession can appreciate and understand just exactly how they would feel, and can, as a whole profession, feel proud that there was not one among them that showed the "white feather." Though they will be like so many in our profession, classed among the unsung

heroes. Nor does the bravery of the Titanic disaster eclipse in any way, the constant bravery and devotion that the medical profession is giving to humanity, without a fear, and with the full knowledge that death at every turn stares them in the face.

Let us stand uncovered and reverential before these unsung heroes.

"Death comes with a crawl or he comes with a pounce.

And whether he's slow or sly,

It isn't the fact that you're dead that counts.

But only, How did you die," —(Cooke)

CURRAN POPE.

PLEURISY.

Pleurisy is often overlooked in infants and in children that it is necessary occasionally to recall its features so that mistakes in diagnosis may be rarer. Before entering upon a disquisition upon this disease it may be noted that the most frequent source of mistake in diagnosis lies in the fact that the so-called pathognomonic symptom of pleuritic effusion in the adult chest, namely the loss of the normal vesicular breathing and voice sounds over the pleural exudate is absent in the case of children. In fact the breath sounds often come to the ear with increased distinctness and bronchial breathing of the most characteristic type is heard with great ease and so one is misled unless one is alive to this deceptive phenomenon. But more of this anon.

Of the usual types of pleurisy, the serous, sero-purulent, the fibrous, etc., we shall find the serous far more frequent in infants and children but it is a question of only a brief period until the serous is converted into the purulent and empyema has resulted often before one has suspected the pleuritis.

Inflammation of the pleura can result from many different causes. By far the most common is the extension of inflammation from the lung to the visceral layer of the pleura which is so intimately connected with the connective tissue stroma of the lung. One might almost say that pleurisy can follow any pneumonic process which has involved the superficial acini of the lung and that it cannot come from a bronchitis because of the intervention of healthy tissue. Pneumonia, broncho-pneumonia, and tuberculosis of the lung are the most frequent factors in these cases. Extension of the inflammation may, however, come from the pericardium or from below the diaphragm as a perinephritic or perihepatic abscess or malignant tumors above or below the diaphragm or from the outside as the result of a traumatism. Finally, there are certain general conditions which act in different ways to produce a pleural effusion, such as scarlet fe-

ver, rheumatism, Bright's disease, and even anemia.

The onset of the disease will be modified by the condition which is causing the pleurisy. If there is an extension of a frank pneumonia there will be much pain, jerky respiration, a sparing of the affected side in breathing, etc. If it follows a less severe process such as Bright's disease or even a tuberculous invasion there may be few if any local symptoms to awake one's attention. The most common history in children will be that the effusion has been preceded by a pneumonia as we find the pneumococcus in the effusion in about one-half the cases. In adults on the other hand the tubercle bacillus is the cause of the effusion in more than on-half the cases and therefore the prognosis of adult pleurisy is not nearly so favorable as in children.

The anamnesis in children will record that the child suffered from pneumonia either lobar or lobular, and that much pain was complained of, which pain is severe and may be referred to remote points. In pneumonia itself the pain may be referred to the epigastrium in such a way as completely to delude us and focus our attention on the stomach instead of the lung. Or the pain may be felt in the arm or shoulder. It is possible to find that pain has been felt and yet that the patient has escaped the pleurisy. But if there is a pneumonia preceding the pleuritis there will certainly be much pain. Children, however, do not localize their pains as do adults and it has seemed to the writer that they often do not make as much complaint as men will. After the pneumonia has reached its crisis there remains some indefinite fever and the cough persists and the patient fails to gain strength rapidly. Then upon examination the presence of an effusion is determined. In the main the symptoms of effusion within the chest are the same as in the adult but there are certain symptoms which are markedly different and about which a few words of caution may be spoken. There is found the same dullness on percussion, with displacement of the abdominal organs and of the heart to the opposite side, the difference in the measurements of the sides of the chest are not so easily obtainable nor is the intercostal bulging so evident, Rauchfus' triangle is easily made out. The coin test is equally helpful. The level of dullness is not so irregular as in the adult chest.

The difficulty arises, however, when we go to confirm these signs by auscultation when often we are surprised and nonplussed to hear bronchial breathing as distinct and as characteristic as in the most unquestioned case of pneumonia. Sometimes the bronchial breathing and bronchophony are just under our ear but usually there is a muffling of the sound

and a far away character to it which is quite diagnostic when one has once learned it.

The prognosis is more favorable in children if recognized and properly treated because of the fact that tubercle bacilli are so infrequently connected with the process.

The treatment of pleurisy is not altogether satisfactory at present. Our efforts should be directed first of all to the relief of pain, which is best accomplished by strapping the chest and the administration of some form of opiate, in small doses; several drugs are credited with modifying the inflammatory process. Aconite or better aconitine, bryonia and in rheumatic cases salicylate of soda, have proven beneficial. Usually the inflammation results in an out-pour of serum, in spite of any furor of treatment. In adults this effusion may remain serous for weeks or even months. In children it practically, invariably becomes purulent before that time. The discussion of empyema may well be left to a subsequent paper. When the effusion collects very rapidly, there is either a marked disturbance of the breathing or a great displacement of the apex beat of the heart, to the right or even to the left. When the lung is contracted down upon the root to the lung and there is no possible expansion for it, then surgical measures must be resorted to for the removal of all or part of the effusion. Incision with drainage seems to give the best results in the young. In pneumococcal pleuritis the removal of small quantities of the serum will often start the process of absorption so that the liquid is rapidly eliminated. It is advisable of course to use iodine secundum artem, with a mild counter-irritant to hasten this process.

The subsequent treatment should look towards securing a perfect expansion of the lung, which has been contracted and perhaps bound down to some extent by the scar tissue, resulting from the organized lymph. For this reason exercise which produces deep breathing will be most helpful.

PHILIP F. BARBOUR.

Iodin in Exanthematous Typhus.—Uffgenauin-off reports fourteen cases which added to Jaworowsky's forty-one brings to fifty-five the number of exanthematous typhus patients treated with tincture of iodine internally, three or four drops three or four times a day, taken in red wine. The disease was unmistakably modified by the medication and evidently much for the better in the entire group, he says.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

RELIABLE MEDICINES.

GYNOVAL is isoborneol isovalerate, $\text{CH}_3\text{CH}(\text{CH}_3)\text{CH}_2\text{COO.C}_{10}\text{H}_{17}$. It is closely related to bornylval (see N. N. R., 1912, p. 49). It is with difficulty soluble in water. The action of gynoval is said to be that of a mild nervine, and antiseptic, resembling that of valerian, with the advantages of a much more agreeable odor and of being better tolerated, especially not giving rise to unpleasant eructations. Like other valerian preparations, it is said to be indicated in nervous headaches, nervous insomnia, nervous disorders of the climacteric, hysteria, cardiac and gastric neuroses and neurasthenia. 0.25 to 0.50 gm. (4 to 8 grains) two to four times daily, best given after meals. Gynoval is marketed in the form of gynoval pearls, containing 0.25 gm. (4 grains) gynoval Farbenfabriken of Elberfeld Co., New York. —(*Jour. A. M. A.*, Feb. 10, 1912, p. 411).

EXSICCATED SODIUM SUCCINATE (*Sodi Succinus Exsiccatus*) is the disodium salt of succinic acid containing not less than 95 per cent. anhydrous sodium succinate, $\text{NaOOC.CH}_2\text{CH}_2\text{COONa}$. It is a white granular odorless powder, possessing a characteristic saline taste. It is readily soluble in water, but insoluble in alcohol, ether and chloroform. It is a saline cathartic claimed by some to have an antiseptic action in the biliary tract and to be useful in combating infections of the gall bladder and biliary passages. Dose 0.3 gm. (5 grains) three or four times a day. Manufactured by Fairchild Bros. & Foster, New York and by Merck & Co., New York. —(*J. A. M. A.*, Feb. 24, 1912, p. 554).

ATOPHAN is 2-phenyl-quinolin-4-carboxylic acid, $\text{C}_6\text{H}_5\text{N.C}_6\text{H}_4\text{CO OH}$, 2:4. The substance was first described by Doelner and Gio-

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

secke in 1887. Its therapeutic action was described by Nicolaier and Dohrn in 1908. It is insoluble in water but readily soluble in alkalis and has a slightly bitter taste. In doses of 0.25 to 0.50 gm. (4 to 8 grains) it increases uric acid excretion, within one hour. In doses of 2 to 3 gm. (30 to 45 grains) the normal average uric acid excretion is doubled and sometimes even trebled in twenty-four hours. Its influence on uric acid excretion is stronger and more prompt than that of sodium salicylate. It does not increase the number of leukocytes, or affect the quantity of urine, or the amount of total nitrogen, purin bases or phosphoric acid.

It is said to be useful in gout, particularly in the acute attacks, acting more promptly than colchicum and without undesirable by-effects. In gout the dose is from 0.5 gm. (7 1-2 grains) four times a day to 1 gm. (15 grains) three times a day suspended in large quantities of water. To prevent the precipitation of free uric acid from the urine, sodium bicarbonate may be administered simultaneously. In articular rheumatism daily doses of 3 to 5 gm. (45 to 75 grains) are prescribed.

Atophan is also marketed in the form of tablets, each tablet containing 0.5 gm. (7 1-2 grains). Schering & Glatz, New York.—(*Jour. A. M. A.*, March 2, 1912, p. 633).

REFORM IN MEDICINES.

PRESCRIPTION NONSENSE.—As an expectorant mixture for children the following prescription has received considerable publicity. It is supposed to be a treatment for bronchitis and bronchial pneumonia in children, and to produce "free expectoration":

"Rx.

Ammonium carbonate	gr. xvi
Wine of ipecac.	zss
Compound syr of squills	zi
Fluidextract of squill	s. c.c
Fluidextract of senega	s. c.c.
Antimony and potassium tart-	
rate	2 gh.
Purified tale	2 gm.
Sugar	75. gm.
Water, to make	100 c.c.
Syrup of senega	zi
Syrup of tolu	ziv
Distilled water	q.s.ad.zii

M. et Sig.: One teaspoonful every two hours for a child two years old."

This prescription is irrational. The chief objection is that ammonium carbonate, which affects the circulation and is irritating to the throat and stomach, is used rather than ammonium chloride, which is a non-irritant stimulant to the mucous membranes. The prescription is unnecessarily complex and con-

tains ingredients that are incompatible, contraindicated and superfluous. It is a nasty mixture which should not be inflicted on a hopeless child. It is to be deplored that such prescriptions are copied and spread broadcast as advice of value.—(*Jour. A. M. A.*, Feb. 10, 1912, p. 410).

SALICYLATES IN SCARLET FEVER.—The recommendation of Dr. F. G. Crookshank (*Practitioner*, Dec. 1910) to administer salicylates or salol to scarlet fever patients as a routine treatment to prevent occurrence of rheumatism as a complication appears to have appealed to medical journals.

Joint rheumatism is a rare complication of scarlet fever, while nephritis is a frequent one and drugs that are used to prevent an improbability should not be so irritant as to aid in producing a frequent probability.

Regarding the recommendation that salol be administered until the patient "reeks of it" it should be remembered that salol (phenyl salicylas) is a compound of phenol and salicylic acid, into which component parts it breaks up in the intestine and hence is liable to cause phenol poisoning. To administer salol to a child with scarlet fever, who is likely to have nephritis as a sequence, is without justification.—(*Jour. A. M. A.*, Feb. 10, 1912, p. 411).

OZONE MYTHS.—Seaside and mountain resorts alike have benefited by the reputation of "ozone in the air" in the neighborhoods involved. The excusable longing of an ever-ailing population for a stimulating atmosphere and for an ideal antiseptic has led many to look hopelessly toward that substance which appears to represent the acme of the valuable properties of oxygen. The honest manufacturer and the medicine faker have both been alert to avail themselves of the opportunity for public service, so that "ozoneizers" and "agonizers" products are displayed in abundance.

It had been hoped that inhalation of ozone-laden air might facilitate oxidation in the tissues, and especially advantageous results were looked for in such conditions as pulmonary tuberculosis, but altogether the results of experiments are disappointing; on the one hand ozone is not the harmless innocuous agent which certain fakers have tried to make us believe and on the other hand inhalations of ozone are much less effective than was thought. Taken altogether it may be said that the value of ozone as a curative agent remains to be proven.—(*Jour. A. M. A.*, Feb. 10, 1912, p. 412).

EFFECT OF STRYCHNINE ON BLOOD-PRESSURE.—Opinion is divided on the question

whether or not the administration of strychnin is followed by a rise in the arterial blood-pressure. Thus while such authority as B. C. Cabot (*Med. Communicat. Mass. Med. Soc.*, 1904, xix, 945) concludes that no rise in blood-pressure occurs, Cook and Briggs (*Johns Hopkins Hospital Reports*, xi, 12) concludes "Strychnin gives a rise in blood-pressure somewhat delayed in onset and lasting from one to four hours. Strychnin is a most satisfactory cardiovascular stimulant for long-continued routine administration, maintaining a satisfactory blood-pressure level free from intervals of depression."

Evidently, the clinical effects of strychnin are in need of further investigation. Exact clinical observations by accurate methods, under a variety of conditions, are needed. Such a study is now being undertaken by a committee of the Council on Pharmacy and Chemistry.—(*Jour. A. M. A.*, Feb. 10, 1912, p. 414).

STUART'S PLASTER-PADS—Adhesif Plaster-Pads, formerly called "Adhesive Plaster Pads," are sold by the Plapso Laboratories, Inc., formerly "The Stuart Plaster Pad Company". It is a "rupture cure" which is advertised not only in the daily papers, including the *Police Gazette*, but also in some medical journals. The claims made for the pads are of the usual "patent-medicine" faker kind and the exploiter has escaped prosecution only on a technicality. Stuart's Plaster-Pads, which are claimed to do in a few days what the most skillful physician and surgeons are unable to accomplish in weeks or even months, consist of a strip of adhesive plaster with a small pad containing a simple ointment. According to a report from the Association's Chemical Laboratory it is a lanolin ointment containing tannic acid and perfumed with oil of pine needles, or some oil with a similar odor and colored dark brown. While in the promotion of this "rupture cure" the use of trusses is severely condemned the Plapso concern, nevertheless, if unable to persuade its prospective dupes to the purchase of its pad will in the end attempt to sell such a truss.—(*Jour. A. M. A.*, Feb. 10, 1912, p. 425).

NOSTRUMS ABROAD—Two recent publications show that the need for restrictions in the sale of nostrums is felt everywhere. A Russian publication, "Where Is the Truth" by Dr. Sokoloff, discusses the means which are being used in Russia to cure the nostrum evil, namely a government control and a requirement to declare the composition of all medicines sold to the public. In his treatment of nostrums Dr. Sokoloff follows a plan of investigation much like that used by the Council on Pharmacy and Chemistry, but his

work is rendered much easier by the energetic cooperation of the Russian government.

The other is the first of a series of pamphlets published by the Central Bureau of Medical Advertising in Sweden. In it the author, Professor Thunberg of Lund, devoted some fifty pages to a plain talk to the public, attempting to prove, by a popular interpretation of certain physiologic and chemical phenomena, the absurdity of patent medicines and the ready-made diagnosis.

It is interesting to note that a part of the methods of attack of the problem in Russia is the autocratic restriction of nostrum advertisements. In more democratic countries on the other hand the growth of public opinion has to be depended on for similar results.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 486 and 510).

PROPRIETARY MANUFACTURERS COMBINE.—The "patent-medicine" makers long ago realized the value of organization and combined to form the Proprietary Association of America which organization has opposed the enactment of laws that should protect the public from the evils of nostrums and quackery. Now the manufacturers of "ethical proprietaries" have organized and formed the National Association of Manufacturers of Medicinal Preparations. Most of the large manufacturing pharmaceutical houses have joined it. This organization, like its "patent-medicine" prototype, has apparently been created with but one object in view, to make money, honestly if possible, but to make money. The association went on record as opposing the modification of the Food and Drugs Act, recommended in President Taft's special message, which would prevent "cancer cure" fakers and others in similarly disreputable businesses from publishing lies on the labels of their nostrums, the Mann bill, which would regulate the transportation of habit-forming drugs, Senate Bill 4727, which would require the weight or measure of all drugs sold in package form to be plainly printed on the label. Finally, the association admitted that it was organized for the purpose of opposing the campaign against ready-made mixtures. The ethical stand of this organization of manufacturers of "ethical proprietaries" does not appear to be any higher than the stand taken by the manufacturers of "patent-medicines"—(*Jour. A. M. A.*, Feb. 17, 1912, p. 487).

"PATENT-MEDICINES" AND THE PUBLIC.—A layman in the sparsely settled state of New Mexico writes in part: " * * * Some time ago, I was talking to a neighbor whose married daughter * * * had been taking Cora B. Miller's headache tablets for some

time. She used them for headaches, pains in any part of the body, even for sleeplessness. Several weeks before she had an ulcerated tooth, and in five days took what was estimated to be over 200 grains of acetanilid—although she did not know it. She had symptoms of acetanilid poisoning. The Cora B. Miller exposure pamphlet, and later the government bulletin on headache remedies caused her to stop at once. She borrowed all the pamphlets I had, had the neighbors read them and even sent the 'Great American Fraud' to her old home. One neighbor threw a bottle of Bromo-Seltzer out at once. • • • • • A similar leaven appears to be working throughout the whole country and it is therefore no wonder that nostrum venders and quacks are moving heaven and earth to discredit the American Medical Association.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 489).

PHARMACEUTICAL MANUFACTURERS AND THE COUNCIL ON PHARMACY AND CHEMISTRY.—The Indiana State Medical Association discusses the relation of pharmaceutical manufacturers to the Council and the profession and states: "The house that refuses to have its products passed on by the Council is not worthy of the patronage of the medical profession, for it can be definitely stated without fear of contradiction that the houses which object to the work of the Council on Pharmacy and Chemistry are not playing fair." It is pointed out that the medical profession should not support houses that refuse to request an examination of their products by the Council for no reputable firm need have any fear because the Council will be sure to give its approval if the representations concerning any product or products are correct.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 501).

WOOD'S CURE FOR DRUNKENNESS.—Edward J. Woods sells from 534 Sixth Avenue, New York City, a mail-order cure for drunkenness; from 1269 Broadway of the same city, he sells a mail-order cure for bald heads as well as a preparation to take the kinks out of the negro's hair. Woods sometimes advertises under the name of a stool-pigeon, Dr. Mary E. Webb, of Boston. Letters sent to Dr. Webb are forwarded to Woods. The nostrum sold by this man as a cure for inebriety, and the man's method of selling it, are discussed. The exploitation is carried on in a style common to mail-order medical fakers: the usual follow-up letters, a sliding scale of prices and testimonials by the ream. Wood also publishes what purport to be analyses of his remedy from individuals who seem to be in the business of furnishing similar certificates to other quacks. An examination of Woods' nostrum showed that it consisted essentially of tar-

tar emetic and sugar of milk. Attention is called to the fact that Woods was recently arrested in New York City for the illegal practice of medicine and was fined the maximum penalty, \$500. In closing it is stated: "Knowing that the chances are not one in a thousand that those who are, in their ignorance, trying secretly to cure members of their immediate family of alcoholism, will be willing to risk the publicity that a demand for the return of their money would bring, Woods calmly continues his nefarious trade unmolested and unafraid."—(*Jour. A. M. A.*, Feb. 17, 1912, p. 502).

FOOD AND DRUGS ACT CONVICTIONS.—The following are frauds exposed under the Pure Food and Drugs Act:

HOXIE'S CROUP REMEDY—"Dr. A. C. Hoxie's Croup Company," Kells Co., Newburg, N. Y., was sold under the claim that it would cure diphtheria and consumption as well as croup, whooping-cough, colds, etc. While the present interpretation of the law permits such lying claims, the product was proven misbranded because the alcohol content had been wrongly declared.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 503).

COCA SALISAYA—Cassebeer's Coca Calisaya Shepard Pharmacal Co., was found to contain over 42 per cent. alcohol, together with sugar, cocaine, quinine and other alkaloids. Although the stuff was plainly misbranded and the Shepard Pharmacal Co., had pleaded guilty for some reason, not evident from the government report, sentence was suspended.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 503).

MORSE'S CREAM.—Morse's Cream, Hazen Morse, New Rochelle, N. Y., was said to be a "Cod Liver Oil Cream" which was "artificially digested" and to possess "10 times greater nutritive value than cod-liver oil." The analysis showed the preparation to be an ordinary cod-liver oil emulsion containing 39 per cent. cod-liver oil and not 67 per cent. as claimed and which had not been artificially digested. The defendant pleaded guilty and was fined.—(*Jour. A. M. A.*, Feb. 17, 1912, p. 503).

FERRO-CHINA ANTIMALARICO.—This product was shipped in interstate commerce by A. Saunig & Co. Although said to be prepared from the "best quality of quinin" and sold as a "cure and preventive of malaria" analysis showed that it contained no quinin.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 571).

WELL'S HAIR BALSAM.—This preparation was made and sold by E. S. Wells, Jersey City, N. J. While claimed not to be a dye and

to contain nothing harmful to the hair or scalp analysis showed it to be a perfumed mixture of sulphur in a watery solution of lead acetate (sugar of lead) and glycerin.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 571).

LAXATIVE BORO PEP-SIN.—A product manufactured by the Senoret Chemical Co., St. Louis. While the name of this nostrum would suggest that it possessed the therapeutic and medicinal properties of boron and pepsin, chemical analysis was unable to detect either substance.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 571).

KENNEDY'S WORM SYRUP, CHERRY BALSAM AND HERCULIN TONIC.—These three products were made and sold by the Dr. David Kennedy Company, Rondout, New York. The "Worm Syrup" while claimed to be perfectly harmless was found to be a solution of santonin (partly deposited), sugar and oil of anise in a mixture of water and alcohol.

"Cherry Balsam" was a "consumption cure" claimed to be "harmless." It was found to contain alcohol, opium, bitter almond oil and sugar and therefore can hardly be held to be harmless.

"Herculin Tonic" is a typical cure-all. Analysis showed it to have, essentially, the following composition: alcohol, 16.00 per cent., quinin 0.065 per cent., sugar 19.98 per cent., water, glycerine and undetermined matter 64.765 per cent. The only medicinal constituent found by analysis was quinin and this only to the extent of .06 per cent.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 571).

IDENTIFYING THE MANUFACTURER.—The National Association of Manufacturers of Medicinal Preparations apparently is opposed to legislation in the interest of public health and safety whenever such legislation would result in decreasing profits for the manufacturers. Besides opposing the law that would prohibit the making of exaggerated and misleading therapeutic claims, the law that would regulate the transportation of habit-forming drugs, the law requiring the weight of drugs, sold in package form, to be printed on the label, it is also opposed to a law that would compel the manufacturers of all medicinal preparations to put their own names on their own products. Those who are familiar with pharmaceutical trade know that very many patent medicines are made by our large pharmaceutical houses and hence it will be understood why this association is opposed to any law that would permit the public and particularly the medical profession, to know the class of trade some of its members cater to. Further those who have followed patent medicine exposures will not be surprised to

learn that the secretary of the National Association of Manufacturers of Medicinal Preparations characterized the bill which would permit the public to identify the manufacturer as a "foolish provision", or that the president of the organization should look on the bill as one "that we can conscientiously oppose." As an illustration of the strange bedfellows made by politics and the nostrum business it is noted that the president of this organization, who thus opposes a law that would throw light on the connection between pharmaceutical manufacturers and the "great American Fraud," was nominated for his position by a manufacturer who has long shouted from the house-tops that he made "no dope for quackery."—(*Jour. A. M. A.*, Feb. 24, 1912, p. 559).

FORMAMINT TABLETS ADVERTISED TO THE PUBLIC.—While in the United States Formamint tablets are advertised in medical journals only, in England they are exploited to the public. As a sign that in due time they will be similarly exploited here it is reported that in Canada they are now advertised in the lay press as a typical patent medicine. Formation of the natural course of events, namely the "ethical" remedy of to-day is the "patent medicine" of the future.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 562 and 572).

AGAR IN THE TREATMENT OF CONSTIPATION AND DIARRHEA.—The use of agar in constipation was suggested by Adolph Schmidt in 1905. Dudley Roberts (*International Clinics*, 1911, IV) finds it of great value in many forms of constipation. It is also of value in the treatment of certain forms of diarrhea. When ingested it causes scarcely any discomfort, and is in no way irritating to the intestine. When taken for constipation it stimulates peristaltic activity by its bulk but no habit is established and when the evacuations become regular it may be discontinued. Roberts has found the dose to be four to eight teaspoonfuls. Adult like the finely cut agar, while children take the ground variety in cereals without objection. It may be taken dry from a spoon and washed down with fluid, but as a rule, is taken better with vegetables, cereals and cooked fruits or with thick sauces. It may also be mixed with the dough of cakes, biscuits and cookies just previous to baking.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 573).

A SHOTGUN FORMULA.—In response to an inquiry as to the quantities of peroxide of zinc, powdered alum, oxid of zinc, ichthyol, phenol, menthol and aromatic oils, to be combined in an ointment, the following criticism is made:

Such a formula, while not absolutely incom-

patible, is too complex; it is a combination of sedatives and stimulants or irritating substances, not all of which are likely to be serviceable in the same case. Before making such a mixture it would be well to consider whether it is the effect of alum, of peroxid of zinc or of ichthyol that is required in the individual case. The use of such a mixture can hardly be regarded as proper treatment either for a condition which requires a sedative or for one which requires a stimulant; and the routine prescribing of such shotgun mixtures is almost as reprehensible as the use of nostrums, the composition of which is unknown; for while one would have a knowledge of what one is giving in the complex formula, the presence of one or another ingredient is practically certain to be overlooked.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 578).

"U. S. P. AND N. F. PROPAGANDA."—To further the intelligent and rational use of medicines, *The Journal of the American Medical Association*, with the assistance of the Council on Pharmacy and Chemistry and of the Chemical Laboratory, has exposed the false claims made in regard to the composition and the action of many proprietary medicines. In so far as it promotes the use of preparations of known composition in place of those of unknown, uncertain or fraudulent character, the medical profession is indebted to pharmacy for the aid which has been given. The medical profession cannot, with good grace, criticize pharmacy for having chosen the path of least resistance when it attempted to wean physicians away from proprietary nostrums by encouraging the use of similar official preparations. There is danger, however, that the pharmacists' propaganda may mean only that the physician who previously used certain proprietaries unceremoniously will be led to use just as unceremoniously the official preparations. Let us hope therefore that those physicians who substitute official preparations for proprietary nostrums will do so with a full realization that they are still in their professional swaddling-clothes and that they should make a serious effort toward individual, rational prescription-writing.—(*Jour. A. M. A.*, March 2, 1912, p. 640).

EZ-X-BA AND PELLAGRACIDE.—Inquiries regarding certain nostrums sold as cures of pellagra were referred to Dr. Reid Hunt of the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service which has for some time been conducting a study of pellagra. EZ-X-BA and Pellagrace are each supplied in the liquid and the tablet form. From the report of the analysis made in the Hygienic Laboratory it appears that the liquid forms of EZ-X-BA and Pellagrace

consist essentially of an aqueous, slightly acid solution of iron, aluminum, magnesium and calcium sulphates. EZ-X-BA and Pellagrace tablets appeared to consist of iron, aluminum, and magnesium sulphate mixed with starch and sugar. A similar preparation could be prepared at a nominal cost from the partially weathered iron-bearing minerals occurring abundantly in the South by digestion with dilute sulphuric acid.—(*Jour. A. M. A.*, March 2, 1912, p. 648).

GODFREY'S CORDIAL.—Another baby has been killed with Godfrey's Cordial. Godfrey's Cordial appears in the National Formulary as a synonym for *Mistura Sassafras et Opii* and a teaspoonful (4 c.c.) contains about 0.12 c.c. (2 minims) of tincture of opium corresponding to about 0.03 gm. (1.5 grain) of opium. The designation of "cordial" to such a dangerous mixture is deplorable for the term cordial gives the impression that the article bearing it is not only harmless but beneficial. It should be omitted from the next issue of the National Formulary or its synonym changed so as to render it less potent for harm.—(*Jour. A. M. A.*, March 2, 1912, p. 650).

FUNDAMENTAL ERRORS IN OUR SYSTEM OF EDUCATION*

By R. J. W. PRYOR, Lexington.

There may be many fundamental errors in our system of education; there may be few. Evidently there are some; hence the interest now manifest in the subject of educational reform.

In treating this subject, I would call your attention to what I consider a fundamental error in our system of education and that is, a failure to appreciate the importance of the "Science which deals with all the influences that improve the inborn qualities of a race," the science of Eugenics, as defined by Sir Francis Galton, and what are those influences that improve the inborn qualities of a race.

Unfortunately many people seem to think that Eugenics is solely concerned with the sterilization of degenerates and the confirmed criminal, and the discussions upon eugenics degenerate to this phase of the subject. Granting its value, this is but a small part of the broad subject that Eugenics must embrace, if we are to consider all the influences that are to improve the inborn qualities of a race.

It seems to me we should begin with a thorough study of the unit of a race, that is, the

*Read before the Fayette County Medical Society.

individual. Hence it is not important that thorough courses in anatomy, physiology and hygiene should be given in the university, the college and the high school? The responsibility of the university and the college are of equal importance with that of the grade and high school, perhaps greater, and it is in the higher institutions that thorough courses in the anatomy, physiology and hygiene of the nervous system should be given.

I have given anatomy the first place, for it seems to me to be a self-evident fact that we should have a thorough knowledge of the organ, without which it would be impossible to understand its functions; otherwise the regulation of which and the rules of condition could not be formulated.

The brain is a very complicated organ and this is not confined to the human by any means. It has been said by experienced psychologists that it is with difficulty that the alienist is enabled to detect and diagnose a departure from the normal. It has been said: "When the attempt was made to analyze the anomalies of conduct in the insane, it became evident that no distinctive qualitative difference separated them in behaviour from normal individuals. In the daily up and down of ordinary life are found the bases of the pathological condition known as the manic-depressive insanity, while in the precocious, bizarre habits of young people and children are recognized the germs of that sad group of cases known as dementia praecox. In the rigid, inflexible opinions so frequently expressed in the discussions of religious and political questions, we find the key explaining the stand-pat position of individuals subject to chronic insane ideas. The individual showing a particular bias or those inoculated with the spirit of excessive partisanship, the sentimentalist, the whole lot of faddists, the doctrinaires, the obstinate and the bigots to a certain extent reflect, but to a less degree some of the mental traits of the paranoic."

Dr. Paton says: "The general tendency of educators to prescribe definite mental tasks in order to increase the efficiency of an organ whose functions they have never seriously studied is analogous to the practice of the physicians of the old school, with their inordinate faith in the specific power of a large number of drugs to cure disease." Again he says: "An education, even if wisely planned and well directed, adds nothing to the natural brain power of the individual; it merely gives his latent faculties an opportunity to develop to their highest point of efficiency." In other words, we inherit just so many brain cells, the number of which we cannot increase, but the quality of which we may greatly modify by nourishment, exercise, education. Thus the principles of Eugenics and Euthenics, heredi-

dity and environment, are the potent factors in the development and welfare of the individual and consequently the race.

We cannot say which is the more important, heredity or environment, or that either of them is the most important. Heredity and environment are interdependent; neither is the more important. Both are indispensable for the production of the highest type of animal or vegetable creation. Both are of vital importance to the well-being of the individual. But the question is asked, what has heredity to do with present conditions? Do we inherit our ancestors' physical, mental and moral traits? I will answer this by saying: We may not in all instances inherit these to the extent that they are apparent, but we do inherit the physical, mental and moral characteristics of our ancestors; and these traits may be modified to a marked degree by environment. These characteristics are inherent in the germ cells of both parents and are united by the process of mitosis in the single fertilized cell, from which each individual is developed. Thus the physical, mental and moral traits of the individual are determined, first by the nature of the heritable traits transmitted from the ancestors; then comes in the influence for good or evil from environment. Of course figs do not grow upon thistles, but witness the thornless cactus, the result of cultivation, environment, education. It has been said that our present system of education has a baneful effect upon the health of the rising generation. This does not seem to be true, in the light of the fact that the length of life has been increasing about seven years within the past generation. But it is not a fact that the vast improvements in sanitary science and preventive medicine are the prime factors in the increase in the length of life, and this may be true, in spite of any system of education that may be in vogue.

Preventive medicine and the conservation of human life is one of the most vital economic questions of the twentieth century. It is my belief that the reason for the apathetic attitude of the public toward the prevention of disease is the lack of confidence in the expressed views of the scientific physician. They do not believe that tuberculosis, typhoid fever, etc., are preventable diseases, they do not believe, or at least they do not fully realize, that in practically every case of typhoid fever, the patient has taken into his own mouth the discharges of some other typhoid case, and that the exercise of a little common sense and diligence would prevent this; they do not believe that the toxins of syphilis and poisons like alcohol, lead, etc., circulating through the blood, will so affect the germ cells that the children of these persons may be imbeciles or epileptics; they do not believe

this, because they *think* they know to the contrary. In some instances they do know that such is their own condition, and *their* children are apparently normal, neither epileptic nor imbeciles, but did they realize that these same children, when mated with one of like inheritance, are just as sure to produce defectives, yes, degenerates, as that daylight and darkness succeed each other, they would *stop to consider*. The time has arrived for the dignified doctor to throw off his robe of reticence and attack with vigor the enemies of progressive and preventive medicine. He must participate in public discussions; he must refute the false statement of so-called reformers—antivivisectionists, anti-vaccinationists—the sentimentalists whose sole delight is in maligning the medical profession.

It is true that it is a most difficult matter to discriminate between the genuine and the quack. It is a failing of human nature for drowning men to catch at straws. I have seen the best of educated and progressive physicians willing to try most any remedy with the hope of obtaining relief, when his mind and judgment were disordered by disease, and you cannot blame the public for this failing. The worst form of a charlatan is the plausible, pleasant, sympathetic and encouraging physician, who makes a diagnosis without difficulty, and proceeds to drug, electrify, etc., until at least the purse of the patient is sufficiently depleted. I have said that physical traits are heritable. All are familiar with the transmission of features, from parent to child—the color of hair and eyes and even peculiarities. But we may go deeper than the surface, to find physical evidence of the inexorable facts of heredity. During a research on the ossification of the bones of the developing child, I have found that normal variations in the ossification of the bones is a heritable trait. In this research I made the following observations:

First. The process of ossification is inaugurated much sooner than hitherto supposed.

Second. The bones of the female ossify in advance of the male. This is measured at first by days, then months, then years.

Third. The chronological order in which the bones of the carpus are ossified is different from that formerly supposed.

Fourth. The bones of the first child, as a rule, ossify sooner than those of subsequent children.

Fifth. Regardless of the variations (normal) the ossification is bilaterally symmetrical.

Sixth. The union of the epiphyses with the shaft takes place much sooner than formerly supposed.

Seventh. Variation in the ossification of bones is a heritable trait.

And this brings me to what I consider a

fundamental error in our system of education, that is, the massing together of children of all degrees of mentality, regardless of their physical condition and making them conform to a single standard. This I think is wrong in principle and in practice.

Dr. Thomas Morgan Rotch, of Harvard Medical College, says: "Up to the present time the age of an individual has been computed by years. This rule will probably always hold good in all civilized communities from a legal point of view. When, however, the question of age is brought to bear on our school systems, whether in classifying and grading children as to their studies, or in pitting them against each other in athletic sports, it becomes a very serious question as to whether chronologic age is a wise division during the formative period of life. Again, when the important question of child labor is brought before us, and we have to determine at what age a child should be allowed to work, and what the degree of that work should be according to the chronologic age, the decision becomes momentous and we can at once see that a chronologic division for this purpose is not only insufficient but clearly pernicious. It behooves us then to look at the question of age in early life, first, from a chronologic point of view manifestly legal; second, as regards athletics, manifestly anatomic; third, educational as regards school grades, manifestly a combination of chronologic, physiologic and anatomic conditions."

With these facts and with the addition of the observations I have made, Dr. Rotch has formulated a table which is based upon the X-ray examination of the wrists of a large number of children. This table represents his anatomic index, which, in connection with physiologic conditions and chronologic age, is used to classify children in their school work, athletic contests and for child labor. Time will not permit of a more extended explanation of this. It is evident that if we expect to accomplish the best results, we must begin at the beginning. How important is the care of the individual during the plastic stage of childhood. Modern psychologists say that comparatively little change in moral bent takes place after adolescence. It is, then, in childhood that physical, mental and moral plasticity is to be reckoned with and taken advantage of if we expect to mold the individual. The education of a child means much more than merely communicating to it the contents of a text-book. Some discretion must be used by the teacher in determining how much study each child is capable of. The physical and mental powers are so interdependent that no system of education, although designed solely to develop mentality, would be complete which ignored health and is it not

true that a physically and morally healthy personality compensates to some extent for a lack of intellectual equipment? The educating of children renders their mental efforts largely dependent upon their physical condition. The teacher should have an accurate knowledge of each child's physical condition. An impaired physical condition implies a perverted mental and perhaps moral condition. A well-nourished body and brain is an essential requisites for mental equilibrium. Hence Juvenal's dictum: "A sound mind in a sound body." The proper mental and moral environment is as essential to the developing character as the proper physical condition is to the body. Intellectual and temperamental differences are influenced by many causes. Imperfect nutrition due to a deficient or defective diet is the cause of irritability to the point of viciousness, or to at least irresponsibility and stupidity. It is a sad fact, but it is true, that the want of discrimination in diet is almost universal.

Note the ideal (?) lunch I had the opportunity of inspecting. While walking down Broadway, a little girl about seven or nine years of age tripped and in falling her lunch basket was emptied. After picking up the child, I assisted in picking up the lunch, which consisted of two hard-boiled eggs, some pieces of cheese and several slices of cake—only the proverbial pickle was needed to complete this ideally indigestible, indiscriminate lunch, evidently prepared by an irresponsible parent or guardian. On another occasion I was fortunate enough to be seated near two mothers—a small child by the side of each—at an afternoon entertainment. One of the children was eating candy the greater part of the time and was beyond the control of the parent and a constant disturbance during the afternoon. The other child was quiet and seemingly contented. I noticed that during an intermission the mother gave *this* child some bread and butter sandwiches. I have no doubt the diet had a great deal to do with the disposition of these children. Many children are mentally backward because they are improperly fed.

We must educate the children from the time they enter the kindergarten, through the grade and the high school, through the college and the university. They must understand and practice the fundamental principles pertaining to clean bodied and clean minds. I would place the latter first, but I fully appreciate the difficulty of maintaining a clean mind in a body of the opposite condition. Has it ever occurred to you that absolute cleanliness means perfect health? Cleanliness is the keystone to sanitation. With absolute cleanliness of body and mind, there would be no popular disease. I refer, of course, to venereal diseases. With absolute cleanliness, tuber-

culosis, typhoid fever and the infectious diseases would disappear from the face of the globe. Cleanness of body and mind cannot be legislated into anyone. It is a question of education and this must begin in the kindergarten, for it is here the foundation is laid, upon which the superstructure is to be erected that determines the future life of the individual, and the welfare of the community. But the most important question and the greatest error in our system of education is the failure to provide instruction in sex hygiene and perhaps in social hygiene. You may ask when and how this should begin. It is unquestionably the duty of every parent to instruct their children in sex hygiene, but they do not do it and how many parents are capable of giving their children instruction on this subject? Unfortunately the large majority of parents are totally incapable of instructing their children, and even those who are capable fail, through some mistaken ideas of propriety and they hesitate to mention such subjects to the supposedly innocent child. The question arises when should this instruction begin?—certainly not in the university or college—provision should be made for a continuation of instruction upon these topics, but it must begin much sooner in life, if anything is to be accomplished. If the principles of physical, mental and moral cleanness were thoroughly instilled in the developing child, the great questions of moral uplift and the greatest question of the present century—that of the white slave traffic—that is eating at the very vitals of civilization—would in a large measure be solved, and we must not close our eyes to the fact that the white slave question is a living one in our own city. The House of Bondage is not a myth. It exists in all large cities. It is said that here are twenty-five thousand public women in the city of Chicago. The life of these unfortunate creatures is about five years, and to maintain this ratio, they are renewed at the rate of five thousand per year. And this is not confined to Chicago. Is it not appalling to know that this condition is universal? Something would be accomplished by vigorously prosecuting, not the poor unfortunate creatures that exist in these places, but publish, prosecute and punish the men who are responsible for this deplorable condition. But, after all, is it not a matter of education? While I do not believe that you can legislate morals into anyone, I am sometimes inclined to think with Parkinson: "The merit of truth is not in its nakedness. To depict in startling colors the awful consequences of vice and to dwell on its equally appalling prevalence have never been found effective in advancing the standards of virtue. Fear of consequence is not the ultimate appeal to a robust nature. No degree of danger will deter a

youth from venturing into experiences which he believes he is to share with those who constitute the real world; and vice always claims to be the real side of human life. Society is so permeated with this tone of patronage toward the poor fellow who has not sown and reaped wild oats, that no threatened consequences can avail much with a youth who would rather be penalized than patronized. The half contemptuous attitude toward innocence maintained so conspicuously by the more outspoken portion of the public, is more impressive to the average youth than all of the public, is more impressive to the average youth than all the scare-heads that benevolence may display in his path. For every man desires to be a sharer with other men. Unless he can be assured that reality reaches as far upward as it does downward, that the upper world is as rich to the explorer as the nether and affords at least equal manly companionship, he will cast his lot with the underworld and take his chance with his fellows in spite of all warning."

CLINICAL MICROSCOPY.*

By MASON COOMBS, Pineville.

Should the physician attempt to diagnose a certain condition without regard for the temperature or pulse rate, or character of the pulse, he might succeed, and he might fail. In some affections they are of little or no significance; in some, absolutely misleading; in others, as for instance, typhoid fever with its typical temperature curve, together with the corresponding low pulse rate, of more aid than any other clinical manifestation. Therefore, to lose sight of either of these valuable indicators would mean that, sooner or later, he would be groping in the dark.

The same is true of the use of the microscope. Although in certain instances, it lends no aid; in others its use enables us to arrive at a definite conclusion; in which cases, without its aid, we are unable to make a diagnosis.

By the use of the microscope alone, we may diagnose many conditions and many other diseases, microscopic findings, together with the clinical manifestations confirm a diagnosis; in which diseases its relative value, as a guide, is second to no consideration.

The primary lesion of syphilis is readily diagnosed by taking from the ulcer a smear of the serum, staining with India ink and finding, under the microscope, the spirillum responsible for this particular disease—*spirochæta pallida*. The diagnosis made, treatment may at once be instituted, without a waste of two to six weeks' time for the eruption to ap-

pear that we may know the suspected ulcer was specific.

The best diagnosticians in this country are not, in all cases, able to differentiate diphtheria from other allied conditions without determining the presence or absence of the bacillus which induces it. Vincent's angina so closely resembles diphtheria that at times it is impossible, without the aid of the microscope, to differentiate the two diseases.

In tubercular lesions of the throat or nose, the macroscopic appearance and clinical symptoms are not sufficiently marked to warrant a diagnosis, whereas the presence of the tubercle bacilli is pathognomonic.

Microscopic examination of the sputum often enables the diagnostician to detect incipient tuberculosis before cavity formation takes place.

In tubercular lesions of the kidney or bladder, a microscopic examination of the centrifugized urine reveals the trouble readily.

But recently, one of the best surgeons in Chicago advised an operation on a physician for appendicitis. So marked were the clinical symptoms that he based his opinion on them alone. Not being willing to subject himself to an operation without first having a more thorough examination, he declined to submit to it, and it was found, after a microscopic examination of his blood and feces, that he had, not appendicitis, but intestinal parasites. There was no polymorphonuclear leucocytosis, which is always present in appendicitis, and the only change in the blood was an increase of the eosinophile ratio. They constituted, in his case, 20 per cent. of the total leucocyte count, as against 1 to 4 per cent. in health. This was strongly indicative of intestinal parasites, which the finding of eggs in the feces confirmed. He was treated accordingly and his symptoms promptly disappeared.

The microscopic examination of the urine is equally as important as the chemical examination. If we have albuminuria, we surely want to know what condition is accountable for it. If in urine which contains albumin, we find, of the casts, only the hyaline type, we know that we have to deal with a parenchymatous inflammation of a mild degree. The presence of epithelial casts would indicate desquamation, and if we find granular casts, we know the kidney is undergoing a process of degeneration. In any of these conditions we may get albuminuria, so when we find albumin in the urine, we should not content ourselves with the knowledge that it is present, but seek to know why it is present.

We all know the value of blood examination in surgical diagnosis; the differential leucocyte count as an index to the severity of infection; the polymorphonuclear ratio, to body resistance, idiophilia reaction to determine the

*Read before the Bell County Medical Society.

presence or absence of pus; as for instance, in appendicitis of the suppurative type, we get a positive iodophilia, whereas in catarrhal appendicitis, with no complication, we invariably get a negative result. In pleurisy, with purulent effusion, iodophilia is positive; with serous effusion, negative. It is to be remembered that this phenomenon occurs in diabetes and a number of the acute infectious diseases.

The Widal test, in suspected typhoid, is best made with the aid of the microscope.

Finding of the plasmodium malarial in the blood is often necessary to diagnose malaria.

It is of unspeakable value in differentiating the anemias and is practically the only means of recognizing lymphatic and myelogenous leukemia.

Below is a list of requisites for practical microscopic work: Microscope, with tripple nose piece, 2 oculars, 3 lenses, 2-3, 1-6 and 1-12, the latter for oil immersion; mechanical stage, hemocytometer, Thoma-Zeiss preferably, Coplin jar, bell jar, for scope; 1-2 gross slides, 1-2 oz. cover lids, 3-4 inch square, No. 1; platinum needle, cornet forceps, alcohol lamp, box for 25 slides, tube Canada balsam, 10 grams Grubler's methylene blue, 10 grams Grubler's eosin a 1 c., 10 grams Bismark brown, 30 c.c. aniline oil, 100 c.c. Loeffler's alkaline methylene blue, 100 c.c. carbol-fuchsin, 1 lb. pure methyl alcohol, 1 bottle oil of cedar, 1 bottle India ink, 1 centrifuge, test tubes, filter paper, a few tubes of blood culture media, 1 tube typhoid bacilli.

I do not think it necessary to have an incubator, as one can make use of his inside vest pocket, or a Thermos bottle for growing cultures.

Excepting blood examinations, any physician should be able to do practical microscopic work, such as he has use for in every day practice. Even the blood work is not difficult. To be able to read the various blood pictures one must first familiarize himself with that of normal blood. He must know the appearance of the normal erythrocytes, and be able to recognize the different types of leucocytes, and their proportions in health. He must be able to make a differential leucocyte count. Finally, he must know any departure from health, as represented by the blood picture, and be acquainted with the conditions which generally produce it. This requires time and painstaking, but it is worth while.

PTOMAIN POISONING.*

By J. M. SALMON, Ashland.

The word ptomain, from the Greek ptoma, a corpse, was coined in 1875 by Selmi, an Italian investigator.

Many years prior to this time, the investigation of Kustner, Schlossberger, Panum, Bence Jones, Bergmann and Sonnenschein had demonstrated that the poisonous principle of putrid meat is a chemical substance, not a living organism.

Nencki and his pupil Brieger first determined the chemical character of these substances, ptomains, by the analysis of a base, $C_8H_{11}N$.

Brieger's researches, the most extensive in the chemistry of ptomains, established the constitution of a number of putrid bases.

The chemical phase of this subject is essentially technical, and therefore of interest to those only who have had special training in bio-chemistry. To physicians generally, however, the salient facts may be expressed by the definition of the term ptomain—"abasic, nitrogenous, organic substance produced by bacteria."

Ptomains have been called animal alkaloids, but this term is not accurate. They are not necessarily produced from animal substances but may be formed by the putrefaction of vegetable proteins. Moreover, they are not always, or even generally alkaloids. Usually they are classed chemically as nonamides, diamines, triamines or amido-acids.

The term ptomain, therefore, applies not to the individuals of a distinct class of chemical compounds, but to the bacterial origin of members of several different chemical functions having in common the two qualities that they contain nitrogen and are basic. (Witt-haus).

Strictly speaking, with regard to the derivation of the word, ptomains are produced only by saprophytic bacteria, either outside the living body or within it; (intestinal putrefaction or gangrene). Recently, however, the basic products of parasitic bacteria are also designated ptomains, or toxins.

The list of ptomains is long and many of them are unimportant and non-poisonous. Those formed by pathogenic bacteria, however, are actively poisonous. Thus tetanin, a ptomain according to the definition given, when injected into animals, produces symptoms similar to those caused by the bacterium themselves. But it has been shown that such ptomains, obtained from cultures of virulent bacteria, are greatly inferior to toxicity to the bacteria-free cultures of the same organisms.

*Read before the Boyd County Medical Society.

The inference, therefore, is plain that these bacteria produce other substances, not yet understood, but commonly termed toxins, which are non-basic, and are the chief agents concerned in bacterial poisoning.

Witthaus classifies ptomaines according to chemical function, as follows:

Monamins, (methylamine, propylamine).

Diamins, (neuridin, saprin, spermin).

Triamins, (methylguanidin).

Hydramins, (cholin, neurin, mosearin).

Betains, Amido-acids (leucin, tyrosin, Alkaloids, the best known of which are indol and skatol.

In addition to these, there are ptomaines of unknown chemical composition such as morphin, typhotoxin, tetanotoxin, tyrotioxin.

Much time and labor have been devoted to the study of the ptomaines, but it still remains to be demonstrated that the ptomaines are, *per se*, responsible for the group of symptoms which we call "ptomain poisoning."

It is probable that the well-known phenomena which follow the ingestion of certain foods is produced by several ingredients of these foods.

These poisonous ingredients may be innate, as leuconains; or they may be derived from external sources. Thus quail, grouse and rabbits are sometimes poisonous because of certain foods eaten by these animals. Usually, however, the development of poisonous properties in foods is due to bacteria, either acting as such, or as toxins elaborated by them.

From the foregoing statements it will be seen that the term "ptomain poisoning" should be abandoned because it is misleading and inaccurate. A better term is "food poisoning" which includes all the various factors concerned.

For practical purposes it is best to study subject of food-poisoning as it applies to each of the common classes of foods.

Among foods of animal origin commonly containing poisonous substances are the various meats as veal, beef, pork, and, rarely, chicken and mutton. These meats may be poisonous either as a result of infection of the animal during life; or because of putrefactive changes due to improper care or curing of the meat.

Meat from diseased animals usually contains organisms of the type of the bacillus paratyphosus, and the toxic symptoms developed in those who eat such meats is really an infection by bacilli of the colon-typhoid group, principally the bacillus enteridis of Gartner, which is closely allied to the bacillus of hog-cholera.

Van Ermengen has shown, however, that meat may be infected with the bacillus paratyphosus after the removal of the meat from

the body. In such cases the meat is often unchanged in taste or appearance, and it's character cannot be determined by the usual tests.

In the form of Wienerwurst and other highly spiced meat mixtures paratyphosus infection is often disseminated. The toxin is highly persistent to heat and therefore may not be rendered innocuous by cooking.

The symptoms of this form of meat poisoning appear after a period of incubation of from two to forty-eight hours. The patient becomes dizzy, nauseated, vomits and is seized with abdominal cramps and diarrhoea. There is usually headache. Fever may or may not be present, petechial skin eruptions may appear, there may be continued fever, enlarged spleen, rose spots, and in short all the symptoms of a mild typhoid infection. The mortality is low, only 2.3 per cent. in 400 cases, and these deaths occurring among infants and the aged.

In 1895 Van Ermengen isolated a large spore-forming, motile and strictly anaerobic bacillus which he named the bacillus botulinus. This organism secretes an intensely powerful toxin which is destroyed by a temperature of 100 C.

The contamination takes place during the curing process and the organism may be carried by flies. Kemper isolated this bacillus from the feces of the hog, thus furnishing an argument against the practice of using the stomach and intestines of the hog as a covering for sausages.

Canned meats have usually been implicated in epidemics of botulism. Blood and liver sausages are especially dangerous.

The symptoms of botulism appear after twelve hours and are expressions of the effects of the toxin on the nervous system and on the heart muscle. Gastro-intestinal symptoms may be present, but are not as a rule prominent. The principle phenomena are dryness of the mouth, diminished secretion of urine or anuria, constipation, dilatation of the pupils, paralysis of accommodation, diplopia, ptosis, ophthalmoplegia, aphonia, difficult deglutition. There is weakness of the heart and general prostration. Fever is absent. The course of the disease is slow and the paralysis may last for months. The mortality ranges from 20 per cent to 40 per cent, and most of the fatalities occur between the second and tenth days. (Lauk).

Meat may be infected with putrefactive organisms, and it's ingestion may be followed by symptoms essentially the same as those of paratyphosus poisoning; but the duration is short—seldom longer than a week—and fatalities are rare. In these cases the offending organisms have been either the bacillus coli communis or the proteus vulgaris.

The flesh and organs of certain varieties of

even healthy fish may contain substances poisonous to man. In Europe the roe of the harel is known to be poisonous during spawning season. The same is true of certain varieties of herring and mackerel. The liver and ovaries of the globe fish family are intensely poisonous.

The poisons referred to are innate (leucemains), and cause two types of disease—gastro-intestinal and nervous.

The gastro-intestinal type is common and requires no special mention. The nervous type is due to poisons which have been isolated from the ovaries of the globe-fish family, found off the coast of Japan and the Malay Archipelago. The best known of these poisons is fagin, which closely resembles curate in its action, causing complete motor paralysis. The majority of those affected by this type of the disease die in from one to three hours after the onset of symptoms.

Most of the instances of fish poisoning have been due to bacterial toxins as described under meat poisoning. In the epidemics reported, the symptoms described are strongly suggestive of botulism although no careful bacterial examination for the bacillus botulinus has been made.

The toxins of putrefactive bacteria in fish cause symptoms similar to paratyphosis infections in meat.

Mussels and oysters which have been taken from contaminated water, sewage, often contain a peculiar toxin or toxins which may cause serious or even fatal poisoning. According to Vaughan the gastro-intestinal form of crustacean poisoning is due to putrefactive poisons, while the paralytic form is due to a special toxin isolated by Brieger, called mytilotoxin.

Milk poisoning (galactotoxismus) and ice-cream or cheese poisoning, (tyrotoxismus) are due to bacteria of the colon group, which, according to Vaughan produces a toxic albumose. In the majority of reported epidemics, investigation of the suspected food has revealed the presence of tyrotoxin, but whether this substance alone, or in conjunction with colon bacteria is responsible for the toxic phenomena is undetermined.

The symptoms of this form of intoxication are apparent within five or six hours after eating the contaminated food.

There is vertigo, nausea, dryness of the throat and burning of the oesophagus and stomach. Chills are not uncommon. Vomiting and purging follow with severe abdominal pains. There is headache and, in bad cases, stupor and convulsions. Numbness and cramps in the feet and limbs may be present and there is occasionally loss of control of

the sphincters. Most cases of milk poisoning recover in a short time and the mortality is almost nil.

PELLAGRA.*

By A. E. THRELKELD, Wheatley.

Pellagra is an endemic trophic disease of toxic origin, with various manifestations, characterized by gastro-intestinal, cerebro-spinal and cutaneous symptoms. The term is from the Italian; pelle (skin) and agra (rough). Pellagra is no new disease. It has existed in Italy and parts of Southern Europe for nearly 300 years. A few isolated cases have been reported in this country for the past thirty years, but it did not exist to any appreciable extent until the year 1907. It prevails mostly in the Southern states, but cases have been reported in thirty different states of the Union.

At present it prevails more or less from central and southern Asia westward to California. Speaking in round numbers there were officially reported in the United States during 1908 1000 cases; in 1909, 5000 cases; in 1910, 10,000 cases. Doubtless there have been many more unrecognized and unreported cases than the number officially reported. Some physicians in a position to competently judge believe there were 100,000 cases during the year 1911. The disease is unquestionably rapidly increasing, and it now bids fair to become a national problem.

The etiology of pellagra is at present unknown. Reed believes the fungus *diploida* are a possible factor; Rohrer thinks it due to the *aspergillus fumigatus*; Auld attributes it to a magnesium infiltration; Fizzoni and Wood have isolated a bacillus which they think the cause; Long believes that amoebae in stools have a definite relation to pellagra; Sambon believes it due to the bite of the sand fly. The only theory of the above which seems likely to be proven correct is that of infection by the simuliid fly, commonly known as the sand-fly.

The result of more recent research work tends to prove that the eating of maize products, either sound or unsound, has nothing to do with the cause, save as the eating of musty or mouldy meal may possibly lessen the normal resistance of the system to the infection.

Story of Sabon (*Jour. A. M. A.*, November 26, 1910, p. 1898) is that the sand-fly after biting a pellagrian and then afterwards biting another person, infects the latter with the toxin of pellagra. The grounds on which Sambon bases his theory are as follows.

(a). The endemic centers of pellagra in

*Read before the Owen County Medical Society.

Italy have remained the same since the disease was first described.

(b). The season of occurrence of pellagra coincides with the season of the appearance of the full-fledged sand-fly, and to the extent that if the spring is early or late, the sand-fly is early or late in appearing, and pellagra cases are correspondingly early or late in their appearance.

(c). In centers of pellagra affection whole families are sometimes attacked simultaneously.

(d). In non-pellagrous districts the disease never spreads to others with the advent of a pellagrin from a pellagrous district.

(e). In the case of a family which has removed from a pellagrous to a non-pellagrous district, the children born in the former district are pellagrins, while the children born subsequent to removal to a non-pellagrous district do not develop the disease.

(f). The disease is not hereditary, although infants a few months old may become infected, especially if taken to the fields in pellagrous districts, when their mothers work during the season when the sand-flies are in evidence.

(g). Pellagra is not contagious, but is transmitted to each individual by an infected sand-fly.

S. J. Hunter (*Journal A. M. A.*, Vol. LVIII page 547) experimenting along this line, transferred a colony of sand-flies to a screened room occupied by a pellagra patient. After the flies had bitten the patient they were transferred to a screened cage containing a monkey. In three weeks the monkey became sick, continued to grow worse, was afterwards killed and an examination of the brain and spinal column showed indications of the pathological lesions of pellagra. Preparations are being made for carrying on valuable research work, along this line the coming season, and this gives us some assurance that in the near future the etiology of pellagra will be placed on a sound scientific basis.

The pathology of pellagra has not been put on a very definite basis. Harris, of Georgia, noted degenerated changes in the chromophilic cells of the cortex of the brain, and the cells of Purkinje of the cerebellum. In the cord cell degeneration is noted and at times this goes to cell destruction.

The symptoms of pellagra are many and of great variety. All ages are susceptible from the infant of three months to extreme old age, the majority of cases, however, occur between the ages of 30 and 40 years. Whites are more susceptible than negroes. Persons living in rural districts are much more frequently infected than those in urban centers. As regards sex probably seventy-five per cent. of cases in this country are females. Of 189

deaths from pellagra reported from Texas, only 36 of these were males. Only 7 of these were between 20 and 50 years of age. This seems to indicate that persons staying the greater part of their time around the house are more liable to become infected. Sanitary environment seems to exert no influence, the rich and poor, and persons in all ranks of society have become infected. The duration of the disease is from a few weeks to seven years and it may exceptionally last longer.

Pellagra occurs in two forms. The acute fulminating variety and the chronic. The fulminating variety runs a course from a few weeks to a few months and is generally fatal. Should a patient survive it will recur the following spring. The chronic form occurs in two types. In one the disease appears in the spring, runs more or less severe course through the summer, has nearly or quite a complete remission during the winter and returns the following spring. In the other, a rare type, exacerbations occur both in the spring and fall with summer and winter remissions.

Generally the first symptoms noted are those of a gastro-intestinal nature followed by cutaneous and nervous manifestations. Stomatitis is an almost constant symptom; tongue red, gums red and spongy; increased flow of saliva, with burning sensation in mouth and throat. More or less vomiting in three-fourths of the cases.

Intestinal symptoms are prominent in practically every case, generally in the form of diarrhoea, very rarely by obstinate constipation. In most cases we have alternate constipation and diarrhoea. The eruption generally appears on backs of hands first, or it may appear first on top of feet and ankles or on the neck. Generally the eruption appears only on parts of the body exposed, but may in old cases spread over different parts of the body. The skin first becomes red and rough, and sometimes small blebs appear; later fissures occur with incrustations, beneath which exudes serum. Desquamation follows with dark brown pigmentation leaving the skin rough.

As a rule the next development is nervous and mental symptoms. The mental symptoms do not develop until late in the history of the case and exceptionally may be so slight as to be overlooked. These symptoms run all the way from a nervous, restless, peevish condition; or deficiency in memory with occasional hallucinations, to active delirium and pronounced mania.

Cramping pains are felt in various parts of the body; generally some headache; lassitude weakness and anemia supervene; pulse increased in frequency, temperature usually normal.

Beverly S. Tucker, Richmond, Va., (*Jour. A. M. A.*, Vol. LVI, p. 246) sent forms con-

taining 100 questions to various physicians reporting cases of pellagra, and his conclusions drawn from these reports gives us some of the most valuable information ever written regarding this malady. His conclusions embrace 29 paragraphs.

1. Pellagra may occur at any age from childhood to old age.

2. In the South although the negro forms the majority of the lower class, yet pellagra is most common in the white.

3. The disease while affecting chiefly the lower classes still occasionally is met with in those of good social and hygienic surroundings.

4. The disease is widely spread and did not occur in local epidemics.

5. The disease in cases reported is more common in the rural districts than in cities.

6. The majority of cases occurred in the spring and early summer.

7. The gastro-intestinal symptoms, especially the diarrhoea are usually the first manifestations of the disease.

8. The ingestion of maize or maize products whether spoiled or not is not alone the cause of pellagra.

9. Patients whose constitutions are depleted by pernicious habits or chronic diseases are not thereby rendered more susceptible to pellagra than those not similarly affected.

10. The backs of the hands are always affected in the cutaneous lesions of pellagra, and the lesions are always symmetrical.

11. Exposure to sun can not account for cutaneous lesions.

12. Stomatitis is almost a constant symptom.

13. The nervous and mental symptoms conform to no known nervous disease or form of insanity.

14. The nervous and mental symptoms form no distinct clinical entity.

15. The eye symptoms are not pathognomonic.

16. Emaciation is practically constant.

17. The special senses are only occasionally affected.

18. Pellagra is not *per se* a febrile disease, and when an elevation of temperature occurs it may frequently be accounted for by a complication.

19. A moderate anaemia is found in most of the cases.

20. The heart, lungs and genito-urinary organs do not seem to be practically affected by pellagra.

21. Examination of urine, feces and blood show nothing pathognomonic.

22. The cause of pellagra is unknown, and the study of these cases throws no positive light on its etiology. Patients may have pella-

gra who do not eat corn products. Sunlight does not account for the condition. In these cases no parasite, toxin, bacteria or insect has been isolated as being the causative factor.

23. The disease is not communicable by ordinary contact.

24. Three great systems are affected, the digestive tract, the cutaneous surface and the cerebro-spinal and peripheral nervous systems, and their involvement seems to be in the order named.

25. Remissions occur in over half the cases.

26. Death frequently occurs in the first attack.

27. It is too early in this country to estimate its mortality. Probably 50 per cent. die in the first two years.

28. In these cases it can not be said that any patient is more than apparently cured, as it may simply be a remission.

29. No specific cure for the disease has been found, and the remedies in general use are of doubtful value.

Since the publication of the above many different drugs have been tried in this disease. Arsenic and atoxyl have been thought to have benefitted some cases; cacodylate of soda and quinine have been tried; hexamethylamine has probably been used more than any other remedy; transfusion has been credited with bringing relief to some desperate cases. Sodium and salvarsan seem to be more efficacious than any remedy yet tried, in some cases.

E. H. Martin, of Hot Springs, Ark., reported to the sixth annual session of the Medical Association of the Southwest on October 10, 1911, his results of the treatment of fifty cases, which seems to bid fair to become an ideal treatment. Time and experience are needed to verify his conclusions. The following are some of the conclusions drawn from the results of his methods:

1. Salvarsan causes no symptoms if properly given to a healthy subject. In short no disease germs, no reaction.

2. The fever following the administration of salvarsan to a case of pellagra, is not due to the drug but to the endotoxins released from the killed germs; and is also diagnostic and prognostic, and further proves beyond doubt that pellagra is a parasitic disease caused by a micro-organism vulnerable to "606".

3. That it is at least reasonable to believe that this organism is a spirochaeta or a spirillum.

4. That the character of the reaction, the duration of the fever especially, shows that the germs of pellagra are located principally in the brain and spinal cord.

5. That the endotoxins released by the destruction of the pellagra germs are so highly toxic to the human host, that the dose of the

drug must be proportioned so as not to destroy too many micro-organisms at one time, or the results may be disastrous to the patient.

6. Salvarsan does not cure a patient in one dose, owing to the invulnerability of the germs at an early stage of development.

7. Prompt disappearance of symptoms shows that the older germs are killed.

8. That small and increasing doses repeated within the time required for the development of the germs from the invulnerable stage to just before the stage of reproduction, give us a reasonable treatment for pellagra, and should offer as much certainty of a cure as quinine in malaria when given with respect to the seventh day.

These conclusions seem to indicate that an ideal method of treatment has been discovered; but lest some physicians might be tempted to try this method without sufficient training in regard to the use of the remedy, I would sound a note of warning that we are dealing with a powerful, deadly drug. A full dose of salvarsan injected intravenously represents an amount of arsenic sufficient to kill fifty men. The technic of the administration must be carried out to perfection in every detail or disastrous results, total blindness or even death may be the result. With perfect technic to proper subjects and with proper intervals no apparent unfavorable symptoms supervene.

Now that pellagra has been raised to the high importance of a national hygienic problem, doubtless many of the obscurities enshrouding it will be removed, and a flood of scientific light will be thrown upon it.

HEPATIC CIRRHOSIS.*

By MAURICE BELL, Monterey.

Hepatic Cirrhosis is a chronic disease of the liver, characterized by a gradual destruction of liver cells and an overgrowth of connective tissue elements, in consequence of which the organ becomes hard and usually small.

The disease occurs most frequently in middle-aged males, but its occurrence in early life is more common than is generally supposed.

The following are the recognized factors in inducing the disease:

1st. Alcohol, the abuse of spirits is the common cause, it is met with oftener in the class who use strong drink continually than with those who abstain from its use, the change results from the irritative effect of the strong solution of alcohol absorbed from the stomach, the fusel oil is supposed to be the offending material, similar effects are doubt-

less produced by other substances such as highly seasoned foods or ptomaines.

2nd. The effect of syphilis produces two forms of cirrhosis, diffused and gummatous.

3rd. Cyanotic congestion. In cases of chronic disease of the heart and lungs the liver is in a condition of persistent venous hyperaemia in consequence of which the central cells of the liver lobules atrophy and there is hyperplasia of the connective tissue.

4th. Malaria. Sclerosis of the liver may follow prolonged malarial poisoning.

5th. Tuberculosis. This rarely if ever is recognized clinically.

6th. In scarlet and typhoid fevers there are localized necrotic areas which must be replaced by connective tissue. In the cirrhosis of early life excluding alcoholic and syphilitic cases, the acute infectious diseases are probably the important antecedents.

7th. Rickets. The enlargement of the liver in this affection is associated with increase in the connective tissue, which surrounds the individual lobules and produces changes in the bile ducts.

8th. Anthracosis. It occasionally happens in coal-miners that the carbon pigment reaches the liver in large quantities, is deposited in the connective tissue about the portal canal, and may lead to a variety of cirrhosis.

Practically on the post-mortem table we see cirrhosis in four well characterized forms: trophic, fatty, hypertrophic, perihepatitis.

In atrophic cirrhosis the organ is greatly reduced in size and may be deformed. The weight is sometimes not more than one to one and one-half pounds. It presents numerous granulations on the surface, is firm, hard and cuts with great resistance. The substance is greenish-yellow islands, surrounded by grayish-white connective tissue.

In fatty cases the fat is increased, the organ is not reduced in size, but is enlarged, smooth or very slightly granular, and resembles an ordinary fatty liver, it occurs most frequently in beer-drinkers.

Hypertrophic Cirrhosis. Enlargement of the liver occurs in the early stage of the ordinary atrophic cirrhosis, but the increase is moderate and largely due to hyperaemia.

In perihepatitis the liver is generally reduced in size, much altered in shape, and everywhere surrounded by a fine, grayish-white membrane, which varies in thickness.

SYMPTOMS.

The abdomen gradually increases to a varied degree. Oedema of the feet may precede or develop with the ascites. The dropsy rarely becomes general. Jaundice is usually slight, the skin has a sallow, slightly icteroid tint. The urine is often reduced in amount and contains urates in abundance, often a

*Read before the Owen County Medical Society.

slight amount of albumen is present, and, if jaundice is intense, tube-casts, the disease may exist without fever but in most cases there is slight fever, from 100 degrees to 102 degrees. Examination in the early stage of the disease may show moderate enlargement of the liver, which may be painful on pressure. Later in the disease the patient is thin, the eyes are sunken, the conjunctiva watery, and the complexion is muddy, or icteroid. On the enlarged abdomen the veins are distended, and dilated veins may surround the navel. When there is much fluid present it is impossible to make a satisfactory examination, but after withdrawal the area of liver dullness is diminished, particularly in the middle line, and on deep pressure the edge of the liver can be detected, and occasionally the hard, firm, and even granular surface.

TREATMENT.

Ordinary cirrhosis of the liver is incurable. The patient should abstain entirely from alcohol, and if possible should take a milk diet, in any case the diet should be nutritious, but not too rich. Measures should be employed to reduce the gastro-intestinal entarrh and the patient should lead a quiet out-of-door life, keep the skin active, the bowels regular, and the urine abundant. In non-syphilitic cases it is useless to give either mercury or iodide of potassium. The ascites should be tapped early and the operation may be repeated as soon as the distention becomes distressing, continuous drainage may be employed. Sulphate of magnesium, elaterium, compound jalap powder, bitartrate of potassium, digitalis, and iodide of potassium, may be given.

MIGRAINE OR HEMICRANIA.*

By Wm. B. SALIN, Owenton.

Migraine is a paroxysmal headache, usually unilateral, and often associated with gastric and visual disturbances, at times continuing only as long as the sun is above the horizon and hence sometimes called sun-pain.

PATHOLOGY.

In the majority of patients the nervous predisposition to migraine is inherited, women and the members of neurotic families are most frequently attacked.

Among the many exciting causes are disturbances of digestion, sexual excesses and eye-strain.

A gouty or rheumatic taint is present in many instances.

Migraine has long been known to be associated with uterine and menstrual disorders.

We often find cases in connection with adenoid growths in the pharynx and particu-

larly with abnormal conditions of the nose, therefore the nostrils should be examined with great care. Sometimes the eating of some particular article of food may be followed by a headache of the hemi-cranial type.

Now, the commonest exciting cause of migraine is overtaxation of the nervous system, and on this account migraine belongs to the worrying and restless period of life and then declines with repose of old age.

SYMPTOMS.

Attacks of migraine occur in irregular paroxysms, the intervals between being free from pain or nervous disturbances. A paroxysm of hemicrania is often preceded for a day or two by a sense of unusual depression, both physical and mental. The paroxysm is frequently ushered in by certain disturbances of vision. Frequently there is spasmodic action of the pupil on the affected side, which dilates and contracts alternately, the condition known as hippus.

There is a feeling of fatigue or mental depression without apparent cause, heaviness over the eyes, flatulency and indigestion. Numbness of the tongue and face and occasionally of the hand and may occur with tingling.

The attack proper is ushered in by chilliness, yawning, nausea, often vomiting and general muscular soreness, flashes before the eyes, vertigo, and pain of a sharp shooting character of great intensity and persistency, localized most frequently over one eye, sometimes in a small spot on the left side and then extending over the entire half of the head. It very seldom affects the right side and still more rarely affects both sides at the same time.

The pain may begin at any time of the day, but usually comes on in the morning.

The pulse generally is slow. The temporal artery on the affected side may be firm and hard and in a condition of arterio-sclerosis.

PROGNOSIS.

Few affections are more prostrating than migraine. The attacks may continue with more or less intensity from a few hours to a couple of days, the average duration being twenty-four hours.

In women the paroxysmal headaches frequently cease after the menopause, but they often continue to have headaches but different in character from those which they formerly suffered, as a rule in both men and women the attacks of migraine are replaced by neuralgia, usually in the supraorbital branch of the fifth nerve, while few cases of true migraine are permanently cured, the affection is free from danger to life, generally the attacks decline as the person advances in years. It being rarely seen after fifty years of age.

*Read before the Owen County Medical Society.

TREATMENT.

Treatment should be directed towards the removal of the condition upon which the attack depends and I believe that prophylaxis is one of the main indications in the treatment of this complaint. Avoidance of excitement, regularity in meals and moderation in diet are important rules. Cases have been greatly benefited by a strict fresh green vegetable diet, avoiding potatoes, corn, cabbage and tomatoes. Diet is a matter of great importance, therefore the digestive abilities of each patient must be carefully studied. What is indigestible for any person is by that person to be avoided, but no special rule for this purpose is found except that if any article, either of food or drink, is tasted again in an eructum from the stomach it is a notice from the stomach that it does not want any more of that stuff. The neurotic patients should be given up tea, coffee and tobacco, yet there are some patients who claim they can ward off an impending attack of migraine by taking one or two cups of strong coffee.

As much out-door exercise is to be taken as possible, and hot baths taken two or three times a week.

The first thing in the medical treatment is to regulate the bowels, to promote intestinal antiseptics and stimulate the liver.

The therapeutics of migraine naturally divides itself into medications for the paroxysm and the treatment during the intervals. The most useful remedies during the intervals are tonics and nervines. In anemic or chlorotic patients, iron and arsenic should be given for a length of time, cod-liver oil if the stomach will tolerate it, is of prime importance.

The hypophosphites of lime, strychnine, iron and quinine is a useful preparation, in some cases the stomach will bear a simple solution of the hypophosphites without sugar better than the syrup and I prefer to give them in this way.

The various salicylates are useful. In this as well as in other varieties of headaches it is of great importance to keep the secretions free and if there is a tendency to constipation mild laxatives should be employed and the occasional use of podophyllin or a mercurial is of advantage.

When the tongue becomes furred and there is a dull headache with loss of appetite, dilute nitro-muriatic acid acts at times as a specific.

During the paroxysm the patient should be kept in bed and absolutely quiet.

For treatment of the paroxysm a large number of remedies have been advised.

The different combinations of the bromides are useful.

The coal-tar products are now greatly em-

ployed in the treatment of headaches of various kinds, those of principal importance are anadol, phenacetine and acetanilid.

Cannabis indica is probably the most satisfactory remedy, in controlling the paroxysm. Extract cannabis indica 1-6 to 1-4 gr. may be combined in a capsule with sodium salicylate or salol after meals. Cannabis indica may be combined with nux vomica and ergotone, especially where there is a hyperemic condition of the brain. Many times we have to use morphia and atropia hypodermically to abort an attack.

Besides the internal remedies of which I have spoken there are a number of external applications, which have given some relief in certain cases. The application of heat or cold to the head sinapisms or other counter irritants.

LACERATION OF PERINEUM; PREVENTION AND TREATMENT.*

By J. C. B. FOSTER, Monterey.

This is a condition that all physicians have encountered, at least if they have done much obstetrical work. These lacerations have been divided by some authors into three classes: complete, incomplete and central; the last named I will not consider from the fact I do not see how there could be a central rupture without first having a tear of the vulva. However we will not take issue with the views of others better qualified than myself making the statement, but will say that I never saw the form of the injury.

The complete form begins at the vulva extending down and through the sphincter ani muscle; the incomplete begins at vulva but not involving the sphincter muscle.

As to the cause of the trouble, I believe that the state of the patient's bowels have something to do with it; having noticed that when constipation existed during the entire pregnancy I almost invariably had some form of laceration usually of the incomplete variety. It is rather difficult to state from personal experience what per cent. of obstetrical cases are victims of this calamity. I believe I would be safe in making the assertion that with myself in cases of primipara one-fifth or perhaps more have in some degree undergone this mishap. I don't think my estimate too high, taking my own cases as a basis from which to draw conclusions.

Other causes might be mentioned, viz.: smallness of vulva and rigidity of muscles.

Complete laceration is far more serious than the incomplete form, often being followed by inability to retain feces which is certainly a deplorable condition; nevertheless

*Read before the Owen County Medical Society.

cases are on record where complete rupture have recovered spontaneously, this is by no means the rule, surgical interference almost invariably being a necessity. The writer had one case of this kind to come under his observation, being called in consultation with two other physicians and the poor, unfortunate victim is to-day a living monument to our discredit, having never been cured. She was operated upon two or three times by a renowned specialist with negative results.

We now pass to that part of our subject designated, "Prevention of Laceration."

In most obstetrical work, or at least some, the practitioner is advised to endeavor to prevent laceration by a method described as supporting the perineum by laying the palm of the hand against the distended structures and making firm pressure against them during labor pains, with the view thereby of mechanically preventing the rupture of the parts. This plan was followed by myself for many years, of late I have abandoned it to a great extent, believing it to be an erroneous idea. It looks unreasonable to expect any mechanical aid to render us any assistance, in fact I believe that we not only fail in this attempt to prevent a tear, but rather favor the production of it, producing increased action of uterus just at a time when the distention of the perineum is likely to prove hurtful. I think that the perineum should be left alone and the head of foetus, or the presenting part, allowed to gradually distend the parts without any mechanical assistance on the part of the doctor.

My view of late is that we should look more towards the relaxation of the perineum, and with this object in mind, we can be of more service to our patient in the way of prevention than any other course we might pursue.

As a means of prevention some have advised incision of perineum to prevent spontaneous laceration. This may be done in safety but I question the advisability of the procedure. I think that it is a duty of every physician who has been called upon to attend a case of confinement, especially if he has been notified a few months prior to confinement, to question the party closely as to the condition of the bowels, and if they are not thoroughly evacuated, should be washed out with enema of soap suds and castor oil and if there seems to be much rigidity of the parts use hot fomentation and liberal use of belladonna ointment applied to parts, by so doing we can accomplish much toward the prevention of lacerated perineum.

As to the treatment of this condition the incomplete variety which includes a greater number of all primiparous cases few escape a slight tear but fortunately for both physician and patient, this kind need little or no

treatment. Keep knees tied together for a few days following confinement, and pay due regard to strict cleanliness, but where the injury is more severe extending down to or involving the sphincter muscle, then an operation of some character is expedient, and should, in our opinion, be done immediately. Some advocate that the operation be delayed for several days until all swelling and inflammation subsides, claiming that the lochial discharges and the puerperal state often prevents successful results. However, we are inclined to take a different view of the matter, and think that immediately after delivery, or as soon as convenient, is the most opportune time to repair the injury done. The sensibility of tissue is deadened by the prolonged distention to which they have been subjected and the sutures can be inserted with little or no pain. The rule being that union by first intention almost invariably follows. Whereas, to prolong the operation the edges of the wound necessitate patching up, also requiring an anesthetic, rendering the operation in every respect a more difficult one.

CROUPOUS PNEUMONIA.*

By J. L. Cox, Campton.

Pneumonia is an acute, croupous inflammation, involving the vesicular structure of the lungs and rendering the part affected impervious to air, and is characterized by a severe chill, headache, fever, thoracic pain, dyspnoea, cough, great prostration, and the rusty sputum.

CAUSES.

Croupous pneumonia is caused by the diplococcus pneumoniae, of Fraenkel, and produces its chief effect upon the lungs; although sometimes other microorganisms seem to occasion typical fibrinous pneumonia, such as the pneumococcus of Friedlander, streptococci, staphylococci, the bacillus of typhoid fever, or influenza, and the bacillus coli communis, and in some cases, of course, there is mixed infection. It is a disease prevalent in all ages, unlike most infectious diseases one attack predisposes to another, and renders an individual more susceptible. The affection is most frequent in winter and sometimes appears in epidemics. Alcoholism is the most common predisposing factor, exposure to draughts of air and cold, gout, rheumatism, diabetes, Bright's disease are also probable causes.

PATHOLOGIC ANATOMY.

The most frequent seat of pneumonia is the lower right lobe, the next is the lower left lobe, the next is the upper right lobe, but in children and the aged this lobe is affected as

*Read before the Wolfe County Medical Society.

frequent as the lower right lobe. The changes are 1st, hyperemia, or stage of engorgement; 2nd, exudation, or red hepatization; 3rd, resolution, or gray hepatization. The stage of hyperemia, which lasts from one to three days, consists in distention of the vessel, lessening the capacity of the air vesicle, the lung has a reddish brown color, is more resistant, is heavier, and having a slight exudation upon the vesicular surface. The same changes take place in the adjacent bronchioles.

Second, The stage of exudation which lasts from three to seven days, consists in the exudation of a viscid, fibrinous fluid containing blood which rapidly coagulates, and when this is completed the lung is red and its elasticity is destroyed.

Third, Resolution, or gray hepatization, which lasts from one to three weeks, follows in the majority of cases. The coagulated exudation undergoing liquefaction and absorption. The cellular element undergoing a fatty degeneration the greater part being absorbed, the remainder expelled during the act of expectoration.

In retarded resolution sometimes portions of the exudation undergo purulent transformation and is called yellow hepatization.

Abscess of the lung may result from the lung structure becoming involved in the purulent disintegration and are sometimes in great numbers which by disintegration coalesce and form one or more large abscesses which open into the bronchi and are expelled, or terminate fatally.

SYMPTOMS.

The affection begins with a severe chill, followed by a rapid rise in temperature, 103 or 104, pulse strong and full but rapid, there is also either a dull or a sharp pain near the nipple, aggravated by pressure, breathing or coughing, shortness of breath, inspiration short and superficial, the expiration accompanied by a grunt or a groan, the number of respirations increasing to 40 or 50 or even higher per minute, causing interruption of speech; the cough at first short, ringing, and harsh followed by a scant frothy expectoration, and about the second day becomes the rusty sputum, the quantity is increased and a yellow color is assumed as the disease advances. In rare instances we have the blood streaked sputum throughout the disease. From the very onset the prostration is of the most pronounced character, the countenance is flushed, especially over the malar bones there are a well defined mahogany blush, the lips are more or less blue, and perhaps may be observed, epistaxis, headache, sleeplessness and gastric disturbance are common, the tongue is coated, the appetite impaired and, there is constipation; delirium is sometimes

present, and when occurring early is a very grave sign; the fever usually reaches its maximum within 24 hours and continues high until either the fifth, seventh, ninth or eleventh day, when a crisis occurs and within 24 hours the symptoms are decidedly lessened, the fever absent, and convalescence is established followed by rapid recovery, occasionally, of course, the termination is by lysis.

I leave out the physical signs, clinical varieties, terminations, differential diagnosis, etc., and take up the more important part, the treatment.

TREATMENT.

If pneumonia be regarded as a constitutional disease, with its local lesion, then the consolidated lung no more calls for treatment than does the typhoid ulcer of the bowels. The general condition of the patient should govern the management of the case and not the local changes in the thorax. A healthy person attacked with a moderately severe case of pneumonia, where there are no complications, requires no more active treatment than any of the so-called self-limited diseases. But, gentlemen, I am of the belief that the proper treatment administered at the proper time, e. g. in the first stages, certainly cuts the disease short or rather aborts it. My plan of treatment is as follows: The patient should be placed at rest in bed in a moderately heated and well ventilated room, and protected from all draughts. The diet should be the most nutritious, such as milk, broths, eggs, etc., and given about every three hours at the onset of the disease while the pain is severe. I always give 1-4 to 1-2 grain of morphine, hypodermically and if the heart is weak from the onset, I also employ glonoin or strychnia, and, gentlemen, let me say right here that it is good practice to continue strychnia throughout an attack of pneumonia. I then give from 5 to 10 grains each of calomel and soda and follow with a saline, give from 2 to 5 grains of quinine every three or four hours, and to give rest and to lessen the pain, you will find that 5 grains of Dover's powders, given every four to six hours, will give better results than any other preparation you can give although we have several others very highly recommended, such as sulphonal, trional, chloral, the bromides, opium, etc., but Dover's powder will also relieve the cramp, to lessen the temperature and irritableness, small doses of tr. aconite combined with sweet spirits of niter and medium doses ofgelseminum, the cotton jacket applied to the chest is very good but poultices are of slight value, unless it is of ice applied directly over the affected area.

In the aged, or those accustomed to the use of alcoholics, stimulation should be kept up

from the beginning of the attack. Other indications would be frequent, feeble, irregular, or intermittent pulse, dicrotic pulse, delirium, muscular tremor, and subsultus, immediately following crisis, and the period of collapse.

During convalescence the diet should be highly nutritious and the general tonics employed, the best of which in this case is the iron quinine et strychnia.

In addition to the foregoing, I would like to report two cases of pneumonia, which have come under my observation, complicating measles. One of which was a very rare case, and extremely interesting. Seen also by my father in consultation, but which at the time it was seen by him it seemed as though recovery was probable, especially to one who had not been in regular attendance, and seen the sudden changes and variations which took place. Boy, 8 years old, took measles, and during the stage of desquamation developed pneumonia fever, which ran a very moderate course, both lungs being affected. The upper lobe of the right lung, and the lower lobe of the left lung. For the first nine days the temperature ranged from 103½ degrees down to 101½ degrees F. On the tenth day the temperature dropped to one below normal, and remained so until the twelfth day, with a pulse rate of from 120 to 140, governed by the amount of fever as to fullness, etc., and the respiration was from 28 to 40 per minute, and when seen on the thirteenth day had developed brain fever, which, by the way, had been showing signs of irritation of the Basilar lobe during the time after convalescence was established from the pneumonia, e. g. at intervals, of course, and I attributed it to worms and gave treatment accordingly, and was rewarded by the passage of about 67 worms in all, and all symptoms of irritation subsided perhaps twenty-four hours before the development of the brain fever. At that time the boy had been confined to his bed a little more than three weeks, and was, of course, weak and emaciated, and my prognosis was grave immediately I saw him after the development of the brain fever, although the best and most reliable routine of treatment, in my opinion, was pursued, but after the first six or eight hours did not respond, but on the contrary gradually lost ground, until the stage of convulsions was reached, and died at the end of the third day.

As my paper is somewhat lengthy I will not go into detail of the second case, but will state that it was a very similar case of pneumonia complicating measles, except the fever ran a much higher course and after convalescence was established, about the end of the eleventh day, went on to an uninterrupted recovery.

CHOLERA INFANTUM.*

By W. H. Hobbs, Rogers.

DEFINITION.

A variety of acute catarrhal enteritis of intense severity corresponding in symptoms and course to cholera morbus in adult but much graver in termination.

It differs from other intestinal troubles and is therefore considered separately.

ETIOLOGY.

The same reasons that would lead us to suspect a specific cause in cholera morbus in man would lead us to suspect a specific cause in cholera infantum in children, but yet none has been found. It generally is ascribed to a toxine generated in the decomposition and fermentation of foods. Since some error of diet is almost always the exciting cause, still there is predisposing causes; namely, extreme hot weather, dentition, or both; bad hygiene, the previous presence of dyspeptic diarrhea, enterocolitis, or a delicate constitution.

Cholera infantum just includes a small per cent of other summer complaints in children, according to Holt, 2-12 to 3 per cent.

MORBID ANATOMY.

There is little of any deviation from the normal appearance in the affected bowel.

SYMPTOMS.

These consist in copious serous stools at first containing some offensive fecal matter, later becoming almost aqueous, being ejected, as a rule, with great force. The stools contain numerous bacteria but no constant bacteria has ever been isolated; there is crampy pains and the limbs are drawn up, or rigidly extended, also high fever reaching 104 to 105 degrees F.

Restlessness is a characteristic symptom; this usually begins with other severe symptoms; the temperature should not be taken in axilla, as it sometimes becomes very misleading; skin sometimes feels cool with a high internal temperature, therefore we should rely on rectal temperature. We also have intense thirst, and the child eagerly drinks water.

We also have obstinate vomiting, which may come on simultaneously with the purging and at first there is some bile in the vomit, but later it becomes serous. Tongue at first is coated but later becomes dry and red, the child rapidly loses strength and weight, the loss of weight in this disease is more rapid than in any other pathological condition of childhood. The restlessness may be succeeded by apathy and indifference, and this condition soon passes into collapse.

*Read before the Lee County Medical Society.

The eyes become sunken, the fontanelles depressed, skin gray or ashen, and when this condition is once seen by a physician is never forgotten; those severe symptoms may subside and a stage of torpor or semi-consciousness may supervene; the head is retracted and convulsions may occur; the breathing may be disturbed, the pupils irregular and the clenching of the fingers. These are the brain symptoms which are at times misleading to the inexperienced, but they are not associated with changes in the brain nor in its meninges, but may be due to toxins developed in the intestines by bacteria.

DIAGNOSIS.

This is not difficult, the serous vomiting and purging, rapid evacuation and prostration and the hyperpyrexia and the nervous symptoms following conferring the diagnosis.

PROGNOSIS.

This should be guarded, and if a prognosis is given let it be a grave one, for in twenty-four to forty-eight hours the child may be dead or it may make a turn for the better. Mortality in this disease is from 60 to 70 per cent. We should be guided in our prognosis by the condition taken in the constitution of the child and the form of attack, etc.

TREATMENT.

First, prophylaxis. Much can be done, all the general rules of infant feeding in summer complaint and other intestinal troubles should be strictly enforced. If this was done and these rules were not so often overlooked by the nurse or sometimes the physician, many children would be spared the dreaded disease.

MEDICINAL TREATMENT.

The best results in this treatment will be gained if we keep in mind that we are not treating intestinal catarrh, nor inflammation, although this may ensue, but we are treating a case of poisoning and the great depression caused by this toxine to the heart and nerve centers and kidneys draw our attention.

The main indications for treatment are:

- 1st. Empty stomach and intestines.
- 2nd. To neutralize the effect of this poison upon the heart and nerve centers.
- 3rd. To supply fluid to the body to make up for the great drain of the discharges.
- 4th. To reduce the temperature.
- 5th. To treat special symptoms as they may arise.

In complying with the first indication, if stomach is not emptied by vomiting wash out the stomach and to clean out the lower bowel a large soft rubber catheter can be used, introduced high up in the colon.

To meet the second indication, there is nothing better that I have ever used than morphia

and atropine hypodermically in doses of morphia gr. 1-70 to atropine gr. 1-600, repeated hourly until the result is obtained that is checking the vomiting and purging. There are lots of other remedies laid down to be given, but as a rule they vomit so frequently that medicine given by mouth does but little good.

The above treatment is contraindicated where the purging is checked, or scant, and where we have drowsiness and stupor.

To meet the third indication, in extreme cases when needed we should inject a half pint to a pint of the normal saline solution into the loose cellular tissue of the thighs, abdomen and back; the above amount should be used every twelve hours or during each twelve hours.

To meet the fourth indication, cold bath is the best to lower the temperature and if we can not give a cold bath use sheets wrung out of cold water and wrap child up in them.

Fifth, to meet special symptoms many stimulants may soon be needed. Brandy, small dose, frequently camphor, strychnin, hypodermically, and in extreme collapse, hot baths, hot-water bottles, mustard paste, etc. When convalescence is established food should be administered with due caution: barley water, small quantities of beef juice, peptonized milk, dilute egg albumen and gradually increase to more solid foods.

GENERAL SYMPTOMATOLOGY AND DIAGNOSIS OF DISEASES OF CHILDREN; WITH DISCUSSION OF COLIC AND SUMMER COMPLAINT.*

By W. C. CONNELLY, Salyersville.

In examination of children, especially those too young to talk intelligently, a method different from that we are accustomed to using in adults must be used. As the young child can tell nothing we must rely on the parent or nurse for the history and we should be careful not to confuse the person giving the history with the questions till she has told all she knows or can think of about the sickness, then with this information we can readily interrogate with questions that will enable us to make a more full and complete history of the child. On the history of the child much depends and we cannot be too careful in obtaining it. Many times a history of the parent is absolutely necessary for positive diagnosis of the disease of the child. If syphilis or tuberculosis is suspected the history of the parent brings out much that would otherwise be hard to determine. As nutrition is such an

*Read before the Magoffin County Medical Society.

important factor and produce such severe and many times obscure symptoms we should obtain all the details concerning the food, whether or not it is being nourished by the mother's milk and if so character and amount of same or if nourished by cow's milk we should acquaint ourselves with the formula and try to determine whether it should be modified, and if so how much and what such changes will produce.

Carefully ascertain the condition of the bowels through the frequency, color and character of the movements. It is also important to find out the condition of the kidneys—frequency and character of the urine should be determined. The history of dentition is very important condition of child during this period and whether or not dentition was abnormal or difficult. All facts relating to the growth and development of the child is important. In obtaining the present illness learn the exact character of its onset, time of duration, presence or absence of fever, restlessness or pain with its character. The position which the child assumes while asleep or awake, its cry, the interest it takes in its surroundings, together with all the special symptoms are of the utmost diagnostic importance. When the illness has lasted sometime or has become actually chronic always inquire into the history of both father and mother for history of syphilis, tuberculosis or other disease which might be inherited. The appearance of the other children, if any, might be helpful in the diagnosis. The posture assumed by a child is quite significant of its condition. Before the age at which a healthy child can sit up it will lie quietly or move its limbs in the same manner as during intrauterine life and it seldom cries except from hunger or when the napkin needs changing. When asleep it may occasionally lie on its back although the usual position is on one or the other side with its thigh, legs and arms flexed. Healthy infants invariably sleep with the mouth closed, breathing through the nose and the breathing is regular, gentle and accompanied with little if any play of the alae of the nose. The most common cause of disturbed sleep in the child, under four months old is indigestion, although as the period of dentition approaches disturbed sleep may be a symptom of the onset of this condition.

Syphilitic or rachitic children are poor sleepers at any age, usually, but most children can be made to sleep better by close attention by the parent through the day as many times they are allowed to fill up on some heavy food before going to sleep or probably, after children are a year or two old, some sudden fright that has occurred during the previous day may cause night terror or nervous excitement.

There are some diseases of children that have a more or less typical posture and expression of the face, as in affections of the gastro-intestinal tract, we find that the child is restless, crying and peevish resembling that of hunger and is kept up except for a few moments after taking food. Then we see rapid emaciation, especially of the face, limbs and all except the belly which becomes larger. The eyes are sunken and staring, with deep hollows surrounding them, due to the absorption of orbital fat and probably also to muscular relaxation. The child gives an appearance of limpness and loss of tone. The expression of the mouth is one of disgust and around it in chronic cases is frequently seen a blue line. In diseases of the respiratory system of which we may consider bronchopneumonia a type, the child's face is flushed, the eyes are bright but the facial expression is dull, anxious and full of pain. While nursing the child drops the nipple frequently to breathe, attempts to cry but catches its breath, suppresses its cry because of its pain and coughs with a short catchy, grunty cough. The cry is short, hoarse, suppressed and intermixed with coughing. The breathing is rapid and labored. The skin is hot and dry and may be pale, reddish or somewhat bluish if cyanosis exists. There are many other diseases with characteristic symptoms as the "mouth-breather" with the dull vacant expression. The looks readily diagnose adenoids. The spinal diseases, meningitis, etc., also have symptoms peculiar to themselves.

In the study of pediatrics we have a clue and a very good one, too, of testing our knowledge of physical diagnosis. We may appreciate a good knowledge of physical diagnosis more in the practice of pediatrics than any other subject, because on examination of the child we must determine the cause and effect without the information that can be had if the subject were older and able to tell us what effect certain principles of physical diagnosis, palpation, percussion, etc., produce. In diagnosis of children's diseases we can well use all the principles of physical diagnosis, inspection, palpation, auscultation, percussion, and mensuration.

The divisions of a child's life is of much importance in the diagnosis and treatment of diseases, for we find certain diseases corresponding with a certain age of the child. The divisions that most authors make in the different stages of the child's life are: 1st, infancy up to the second year; 2nd, childhood from two to six and a half years, and 3rd, youth from six and a half years to puberty. Taking this division I have classified the diseases of the child as follows:

1st. Infancy, (up to second year) we have

to deal with asphyxia, cutting the cord, caput-succedaneum, cephalo-hematoma, care of child for first month, cries of children, colic, cold, thrush, croup, infant feeding, cutting of teeth, and rickets.

2nd. Childhood, (from two to six and a half years) we find cholera infantum, summer complaint, gastric troubles (of all kinds), worms, diphtheria, emuresis, and nervous diseases.

3rd. Youth, (from six and a half to puberty), we find: The various contagious diseases, meningitis, tuberculosis, rheumatism, erysipelas, and eczema.

We, of course, do not always find the different diseases under this particular classification but generally speaking I think we find them about in this order, anyway for the sake of classification I have so divided them.

COLIC.

There is no disease that causes so much suffering to the child, for the first few months, and perhaps the first year, as colic. This being true we should make every effort to determine just what is causing the trouble and try, if possible, to correct it. Colic is usually caused by flatulence due to undigested food—chiefly milk too rich in proteids, or if milk is over rich in fats it will cause colic. It is considerably more frequent in bottle-fed babies than those fed from the breast although we find it among children raised from the breast, if the natural milk supply is limited in quantity or if the colostrum milk has lasted beyond the usual period, or the diseased mother's milk will give the child colic. Pregnancy or menstruation in the mother may cause her milk to give the child colic or letting the child nurse soon after sexual intercourse may give the child colic. Or on the part of the child a natural enfeebled digestive tract or general nervous system is a predisposing cause of colic as is also dentition.

The cry of colic is very loud and the knees are flexed on the abdomen, cold hands and feet, abdomen tense and the eyes are usually closed. The child invariably wants to nurse or eat and on taking warm food it may be relieved for a few moments but in a short time it returns more violently than before.

TREATMENT.

First relieve the child of its present pain and then remove the cause if you can determine it. Colic in the stomach may be relieved by sitting the child upright so the gas can escape and give it very hot water or hold the child in the arms with abdomen over shoulder and tap it on the back. If this does not relieve it a few drops of Hoffman's anodyne or camphorated tinct. of opium will relieve it, or an enema of half pint of luke warm water, or

some turpentine and glycerine or some asafoetida may be added. Then the bowels should be regulated with small doses of castor oil or some laxative should be given and if this fails to give relief we are pretty certain that the colic is due to too much casein in the milk. This may be met very promptly by the following formula:

R.

Sodii. Phosphatesdr. i
Syr. Rhei. aromat.ozs. ii
M. ft. sol.

Sig. drs. one every two hours.

This usually gives results in two or three doses after an attack. Small doses of calomel are recommended by some and pepsin and sodium bicarb. between attacks if child has weak digestion.

Attention to the food, properly regulating diet, the colic usually disappears of itself.

SUMMER COMPLAINT.

It occurs in summer time and is due to bacterial growth, and usually enters the system through the milk. The bacteria first produce changes in the milk and then act on the mucous membrane. The stools are green, very frequent, and have bad odor.

TREATMENT.

First get rid of the bacteria by giving castor oil; second, keep the bacteria out; third, destroy those that are in the bowel by making the culture media unfavorable to their growth. Then take away the albuminous diet, but if the stools are very acid you had better stop the sugar and it is well to stop all food for twelve hours, then give food different from that which has been given. Barley water and rice water for twenty-four hours are good, but if the stools are very acid put back on albuminous diet again.

For frequent, offensive stools give:

R.

Calomelgr. i
Bis. Subnitratedr. ii
Pepsin Sacch.dr. i
M. ft. powders No. xii. Sig. one every two hours.

Bismuth is very fine as we know that bismuth subnitrate breaks up into bismuth and nitric acid and bismuth subcarbonate breaks up into bismuth and carbonic acid and bismuth subgallate breaks into bismuth and gallic acid and bismuth salicylate into bismuth and salicylic acid. As they serve as the best antiseptic they are very essential in the treatment of summer complaint.

A very fine prescription is:

- R.
 Saloldrams ss
 Glycothymolinedrams iv
 Bis. Subnitratedrams ii
 Elixir Lac. pep.qs. ad oz. ij
 Sig. Teaspoonful every two hours.

For liquid stools the following is good:

- R.
 Bis. Subnitrate.....drams. iij
 Tanalbindrams. ss
 Mucilage acaciaeoz. ss
 Elixir peptenzine qs. ad ozs ii
 M. ft. Mixture.

Sig. Drs. one every two hours.

The above is to stop liquid stools at night when no antiseptic is wanted.

And another very fine prescription is:

- R.
 Sodii Sulphocarbolate .i.gr. xij
 Sodii Carbouatisgr. xij
 Wine of ipecacdr. ss.
 Tr. Hydrastisdr. i
 Syr. Rhei Aromat. qs. ad oz. ij
 M. ft. Sol.

Sig. Teaspoonful every two hours.

Hydrastis is very valuable in catarrhal mucous membranes, and all other inflammations as a tonic. After this prescription give sulphocarbolate of zinc in doses of about one-eighth to one-sixth grains at a dose every three hours, as this is better than bismuth as a an astringent.

THE RELATIVE DUTY OF THE MINISTER.*

By REV. W. J. MAHONEY, Madisonville.

I accepted the assignment of this subject several days ago and fully expected to be prepared for its discussion. However, because of the press of my various duties, I am here without a prepared paper. I want to suggest, though, some things which have occurred to me. I may say in the beginning that this is a subject about which I know very little and I am not qualified to discuss it elaborately. I asked my friend, Dr. Sory, to give me a few points that would be of help to me, but he had no suggestions to offer.

First. That the ministry must have some intelligence concerning the conditions and ills that affect the public health. This must be more or less general since he cannot specialize as does the physician. It is the physician's business to know so that he may deal intelligently with these conditions and remedy these ills. The minister, as a public servant, should seek information that he may intelligently co-

operate with the physician when necessity and opportunity arises.

One thing that has interested me in the last few years, particularly, is the spread of tuberculosis. I believe that the ministry needs to know as much as can be learned, in a general way, concerning the infectious character of this dread disease as well as the conditions favorable to its rise and spread. I have sought to inform myself as fully as is possible for me to ascertain the facts in the case. Dr. Sory will tell you that I am constantly asking him questions and reading his medical journals upon this subject. I read and discuss, as often as I get the opportunity, concerning the general nature and infectious tendency of this disease for the reason that I want to contribute my mite toward improving the conditions and aid in preventing the spread of the White Plague. I am told that correct measures can be employed and hygienic improvements can be made looking toward the decrease and prevention of this disease. The ministry ought to know this and if they are so informed they can effectively aid the medical profession in preventing the spread of this disease.

Second. He said that the ministry needed to be appreciative of the responsibility, the sacrifice and the efficiency of the physician,—and emphasized the fact that the Savior was the greatest physician; that He not only preached and taught but healed many who were sick. The speaker dwelt upon the point that the physician who had caught a true vision of his calling accounted it a ministry unto the Lord; that the greatest factor in the world next to a truly consecrated minister, is a consecrated Christian physician in the office and in the sick room; that the Christian physician can make and should make his work coordinate with the work of the ministry.

Third. He spoke of the *co-operation* that should exist between the ministry and the physician in matters of public health; that the voice of the pulpit assists in enforcing the voice of the physician; that in visiting the sick of his congregation, he always asked the name of the practicing physician and spoke a word of praise as to the ability and merits of the physician that he might inspire even greater confidence in the physician—the word of depreciation should always be withheld. The minister, in his visits to the sick, should always be sunny and sympathetic, not doleful and funereal.

[The stenographer failed to get much that was said by Mr. Mahoney, because of the rapidity with which he spoke.]

*Read before the Hopkins County Medical Society.

THE RELATIVE DUTY OF THE DENTIST.*

By E. B. HARDIN, Madisonville.

What are dentists as a profession doing to advance their specialty in relation to the general health of the nation? I hold every man is a debtor to his own calling, profession or a vocation in life, makes no difference what it may be. In this the twelfth year of the Twentieth Century, we are living in an age of absorbing anxiety of specializing and its not in a degree of egotism, spirit of bragadocio or bravado that I assert to you, that the profession of Dental Surgery is to-day second to no specialty on earth and we only pay homage or profound respects to one greater profession when it comes to the preservation of human life, and that is to the general practitioner of medicine.

In no branch of science to-day is there such an awakening as in medicine. We can only judge people by what they might be, not what they are or will be. It has been said that it is only the ignorant who despise education. Now in these stirring times of medical activity and progressive evolution, the question naturally asked is, "What is the dental profession doing in the great work of elevating conditions, sanitary, physical and mental for the promotion of health for the masses?" Well, we dentists are sentinels as it were, standing guard at the very orifice of the human anatomy, right at the threshold of the so much talked of alimentary canal. We claim good teeth are the first step to good health, and bad teeth are very instrumental in the cause of ill health, for it is within the oral cavity where food comes in contact with the first essential in the great process of digestion, and if our food is not thoroughly and properly masticated before leaving the mechanism nature intended for that work, we can hardly hope for, nor reasonably expect it digested and assimilated after reaching the stomach. Hence it is of paramount importance that the dentist be consulted at regular intervals and a minute detailed inspection made of the mouth and such treatment and repairs as he may advise, be submitted to.

As a profession, we appeal not to the individual alone, but to the parents in behalf of the children for the future welfare of their teeth; care and attention to the deciduous or milk teeth, not for comfort to the little patient for the time being, but to insure beauty, contact, occlusion, approximation and efficiency in the permanent arch. In the cities where dental inspection and dental service has been inaugurated in the public schools and the necessary work done, reports and statistics go

to show an increase of from 10 per cent. to 20 per cent. in general deportment both mental and physical in those so treated.

We dentists stand to-day as we have always done with uncovered heads to our older brothers, the medical men, and we can, and will co-operate, stand shoulder to shoulder with them, also the teachers in our public schools and colleges, the ministers throughout the country and all others who are enlisted in the noble and glorious work of building up the public health, thereby preserving and prolonging life. You may think it absurd, but not ten persons out of thirty in adult life have a perfectly healthy mouth, and not one out of ten has a mouth clear and free from pus at anytime. We as a profession can prove this. Now with all the scare of germ life, bacteria, the parasite and bugology handed us by the bacteriologist, pathologist about the tubercular bacillus of consumption, pneumococcus of pneumonia, the streptococcus pyogenes aureus, etc. Now as we know the normal saliva to be a splendid medium for multiplying germ life as to temperature, and when the mouth becomes abnormal by the presence of cavities and dental caries, gingivitis or inflamed and ulcerated gum tissue, through neglect, it serves as an ideal incubator for producing micro-organisms, and with a mouth full of countless millions of germs, how can we hope to eradicate them successfully, only by the aid of the dentist.

We American dentists claim to lead the combined world in our science, and to-day we present an array 40,000 strong ready, willing and delighted with our electric appliances, hoe, shovel and hatchet, excavators, etc., to help you clean out, clean up and repair, treat the gums, the oral mucous membrane, fill cavities, crown broken down roots and in every way adjust them for the purpose for which nature intended.

With the aid and instruction of our late chief chemist at Washington, D. C., the renowned Dr. H. W. Wiley and one Horace Fletcher of which the associated press and current literature is clamoring so much on what, when, where and how to eat, we as enlightened people ought to feel justly proud of our national ethical dental fraternity and look to them as friends in need and indeed, and we who constitute the profession, using the language of the apostle Paul who ought to have been free from debt, yet during the epoch and reign of Saul of Tarsus said he was a debtor to everybody, both Greek and Barbarian, and as a profession we owe a debt of gratitude to the world at large who have so loyally stood by us during our experimental stage, helped us as an embryo, patronized us as an infant until now we stand alone one of the leading arts of modern times. (Our work

*Read before the Hopkins County Medical Society.

is an epistle known and read of all men). Nor does our debt consist of gratitude alone. We should study to show ourselves approved unto our clientele, be workmen that needeth not to be ashamed, desirous of being real benefactors to mankind, giving to our patients what we would want if we ourselves were the victim. It is said by our medical brother that to laugh, to be happy and mirthful aids health. We think so and as dentists claim to be laugh and smile producers (of course, everybody won't agree.)

Now if you have pretty, immaculate, white teeth, you covet a smile. It is said life is only a joke to the girl with good teeth. Learn to laugh and develop the laughing muscles, it will save you from indigestion or cure you if you have it. We preach laughing, it requires good teeth to be a good laugh.

THE RELATIVE DUTY OF THE PHYSICIAN.*

By L. E. NICHOLS, Nebo.

The building of a perfect body, crowned by a perfect brain, is at once the greatest earthly problem and the grandest hope of the race. If the mind which rules the body, ever so far forgets itself as to trample on its slave, the slave will never be generous enough to forgive the offense, but will rise up and smite the oppressor. The morality of clean blood ought to be one of the first lessons taught by our teachers and ministers. The care of the health is a moral and religious duty. Life is not only to live but to live well.

Teach the children to-day what we, yesterday did not know about the cause and prevention of disease, that the people of Kentucky, to-morrow, may live longer, freer from disease, and be able to carry on the warfare against disease with less opposition from the ignorant.

It being my mission to discuss the cause and prevention of disease from the standpoint of the physician, I wish first to make this statement: "That physicians have done more than all others combined, to promote the health and general welfare of the people." In order to establish this I wish to bring to bear a few facts regarding his life and life work.

We will only go back a few generations when it was the duty of the physician to visit the sick, study the symptoms and treatment and prescribe accordingly. At that time he had done his whole duty, never stopping to consider the why and the wherefores of the disease, consequently, the exact cause of but very few diseases were known at that time.

It remained for the last quarter of the nineteenth century to produce the immortal "Robert Koch" who in the autumn of 1882 an-

nounced to the medical profession his discovery of the tubercular bacilli, as being the exact cause of tuberculosis. He further demonstrated, that this particular microorganism, is present in every case of tuberculosis, and that it is the exact cause of this terrible disease. From this startling and supremely important discovery, there dawned a new era on the medical world, and almost immediately bacteriology sprang into existence, and physicians everywhere got busy trying to find the exact cause of every disease with which humanity is affected, with the result, that they learned the exact cause of almost every disease, and thereby preventive medicine was born.

Already, the great work of physicians, is being felt and appreciated by the people. They succeeded in getting the pure food and drug law passed by the national congress, the vital statistics law of Kentucky, so recently put into operation, is the result of physician's labors. But still they are not done, for to-day they are haunting the lobbies and halls of Congress and the various state legislatures, and the daily mails are being flooded by physicians asking senators and representatives to act upon much needed health laws. These reforms have come and others must follow, but they come only by the hardest kind of pleading, self denials and efforts of the medical profession. This altruism on the part of the profession is regarded by many as an effort to establish a doctors' trust, and on the very threshold of this great undertaking, we are met by organized resistance. A few pious though misguided people, have allied themselves with irregulars, quacks and the great patent medicine interest, and have formed a so-called "League of medical freedom," the sole object of which is to perpetuate the patent medicine interest, and leave unmolested the charlatans whose end and aims are to rob the sick and afflicted, and who are to-day a menace to the happiness and wellbeing of mankind.

Another cause of the slow progress made before legislative bodies and courts in earlier days, was, we were confronted by otherwise broad and fairminded men, with distrust, bias, and prejudice against the medical profession, and everything a doctor proposed. Medical committees visiting the national and state capitals year by year, at their own expense asking legislation against their own personal interest, often had to face this sentiment, even in men of broad culture, large experience and of great liberality on all other questions.

It soon developed that this could be traced to dissensions and jealousies between physicians of all schools and creeds, and practically always, that that particular legislator had had his confidence in the profession destroyed by

*Read before the Hopkins County Medical Society.

the criticism of all the others of the community by his family physician. Of course each one stood high with his clientele but the profession as a whole occupied a very low place in the public esteem. A study of medical history, shows that this evil was handed down to us for centuries, cursing us and the people led by us and dependent upon us. But a few years since the medical profession was aroused to the enormity of this evil, and to its baneful effects upon it and the people and probably never before in the history of the world did a reform so sweep a profession, as that for the elimination of this evil, did ours, and to-day, regardless of isms, fads, and pathies, ours is becoming one of the most harmonious of all vocations.

It can readily be seen, that the same revolution is rapidly going on in the practice of medicine that took place in the practice of law only a few years since. A generation ago, the practice of law was limited to litigations before the various courts and tribunals of the country, but how is it to-day? Trusts, corporations, and business firms, of almost every variety, employ counsel, not to plead their cases before courts and juries, but what for? To keep them out of the courts. And so it is with the practice of medicine to-day. The current of thought is not how to cure a case of typhoid fever, but how to prevent it entirely and finally place it in a list with that once most loathsome and dreaded disease, smallpox, and eventually eradicate them entirely. Of course all sickness can not be prevented by present knowledge, but many of the domestic pestilences that are most dangerous to children and young people can, and the list should be extended by scientific research work. Such extension of knowledge would soon eliminate quackery, the nostrum, and many other similar evils, which thrive by preying upon the ignorance of the afflicted. But listen. It will take years of consecrated unselfish labor, for the medical profession and the laymen, that may be induced to enlist, often in the face of misrepresentation and abuse, which are inseparable from such a reform.

I say the doctors must lead in this work, because they have the knowledge which, not only fits them, but makes it their duty to do so. I am certainly glad to know and realize that we are to-day, taking our first steps in this great work, and we are most fortunate in having this array of lawyers, ministers and teachers to hold us up that our tottering footsteps may not err.

Of course, we regard the investigation of the great trusts by the congressional committee, the election of United States Senators by popular vote, the revision of the tariff schedule, the government ownership of railroad,

telephone, telegraph systems, all questions of vast importance but to my mind these pale into insignificance when compared to the one great question of saving society from degeneracy, and premature decay. To-day our charitable institutions and prisons are filled to the overflowing, and why? Plainly, because there has been no attention paid to marriage laws, and the prevention of the multiplication of the idiot, the imbecile, and the criminal. When we are confronted by these facts, the burning question at once arises, "What must we do to be saved?"

At the beginning of our government the conditions were such that the law-making part could best be conducted by lawyers, but to-day things are different, and what we need first, is more doctors, ministers and teachers in the legislative halls. Why? For to-day reforms in our school system, health boards and medical inspectors, are even more important than courts, judges and juries. They are more important just in that proportion that human lives, human health and happiness is more important than any mere property interest. This fact must be appreciated before the appalling waste of human life and health, and the only important economic drain consequent thereto can be stopped.

In the last ten years the government, through the department of agriculture, has expended millions of dollars, trying to stamp out the Texas fever in cattle, scabies in sheep, cholera in hogs, the various pests of cotton, wheat, corn, and all other agricultural products, and think of how much it has expended for the prevention and cure of human ailments and ills. Not one penny.

What we want, then, is a central department at Washington, presided over by some good old country doctor from Kentucky. And if he come from Hopkins county, we will only know that he is a man of ability and above reproach, that he may be entitled to sit in the President's Cabinet, the greatest deliberative body in the world, and there, with one arm of this mighty government, that will reach from the Atlantic to the Pacific, from the great Lakes to the Gulf of Mexico, from the depths of the lowest slums of our great eastern cities, to the summit of Pike's Peak, and there protect the lives and health of this great mass of humanity, and as a result thereof bring much peace and joy and happiness to millions of American homes.

Of course our state boards will be endowed with greater power and in each county we will have a health officer, who will devote his whole time to the County Hospital, and the inspection of our public schools in general, he will look after the sanitary and all other conditions pertaining to the health of the people. He must receive his pecuniary reward from the

state or county, because the vocation of health officer and medical practitioner are distinctly incompatible. It would be as reasonable to ask judges who sit on the bench, and support themselves in the meantime by the practice of law, as to expect health officers to do effective work while engaged in the practice of medicine.

Experience has shown that if he had the time for practice he would be compelled to give such offense to his patrons, in the enforcement of sanitary and health laws, that he would soon have no practice.

He should have at his command, a properly equipped laboratory, to which any citizen might bring specimens of water, milk, or anything he might consider dangerous to his family, and have it analyzed, without personal expense. He should make such frequent and systematic examination of all school children as to at least afford them an opportunity for the cure of those physical defects which deprive so many children of the chance of an education, and make them invalids for life.

I repeat, that a health building, properly equipped, is just as important in any city or county, as the city hall or court house, and the health officer with an intelligent corps of assistants, just as important as the sheriff, the police, or fire department.

We have said a great deal regarding the medical profession and health boards, I now wish to discuss for a few moments the conditions that now exist and that must be relieved, and more especially, the defective children of school age.

During the past half decade, our educators and investigators in the field of pedagogy, and psychology, have been striving with parents and guardians, in fact all people interested in the care and welfare of children, to give more time and attention to the defective child. As a matter of fact, few questions are of greater importance, for defective in the sense here employed, means any and every form of mental and physical deficiency, which in any way handicaps an individual, or impairs his usefulness in any degree. Not only the welfare and happiness of the child itself but such children, are of especial economic importance, not alone because of his condition, society is deprived of benefits, that would have accrued had he been normal, but too often because his abnormality makes him such a burden to his family, that it is often deprived of social benefits of one or more healthy individuals of the family. Therefore, the effects of child deficiency are only too apparent, and the facts that unfold themselves as one begins to study the problem, are little less than startling.

For instance; careful examination of young men and women, seeking to enter the colleges

of the country, show physical deformity, in over 70 per cent. These defects include: "Spinal curvature, adenoids, mouth breathing, deafness, defective vision, bad teeth, and all manner of chronic affections, ranging from chronic catarrh to active tuberculosis."

Only recently announcement was made in the *New York Times* of the examination of the school children of Boston, Mass., supposedly one of the most favorable localities for human existence.

Of the 42,750 children examined by Dr. Galivan only 14,957 or 35 per cent. were found to be physically normal healthy children; 27,795 or 65 per cent. were found to be below par. These defects were as follows: Mental deficiency, 223; defective nasal breathing, 3562; hypertrophied tonsils, 9738; defective teeth, 19518; defective palate, 86; cervical glands, 4425; pulmonary disease, 456; cardiac disease, 1129; nervous disease, 213; orthopedic defects, 521; skin diseases, 3509; rickets, 575; malnutrition, 1611.

As most of these conditions could have been prevented, had they been detected early enough, and submitted to proper treatment. The question that confronts us—not only from an economical and social standpoint—but humane as well, are what can be done to reduce this condition and how are we to reach them at an age when we can accomplish most?

SOLUTION.

The solution of this problem therefore seems to depend largely upon the efficiency of the school, the teacher and school physician, if these factors are equal to the opportunities before them; and school hygiene can remain uncontaminated from isms and fads and go on and accomplish what has already been shown to lie within its power. We may confidently expect a remarkable and gratifying decrease in these poor unfortunate who are to-day mute but eloquent testimonials to some one's ignorance and neglect.

There are many other preventable diseases which a great deal might be said about, such as typhoid fever, smallpox, measles, scarlet fever, dysentery and the diarrheas and tuberculosis, but time forbids only a mere mention. It is said by Mr. Rush, of Yale, that the average life can be extended 15 years by preventing these diseases.

In conclusion I wish to repeat, this great work must be accomplished by public education led by the medical profession and assisted by the teachers and ministers, it must be carried on by public meetings and public addresses. I say these three professions must bear the bulk of the burden because their vocation pertains to deal with the three great questions of life. "The building and keeping of a perfect body." "The crowning it with

a perfect brain," and "The saving of the immortal souls."

And I honestly and truly have such faith that every member of each profession that enters into his lifework with a heart full of love for mankind and an indefatigable effort to bear his share of the burden, that when the wings of time have wafted their battle-scarred vessels across the ocean of life, that we will be permitted to cast anchor at the portals of the New Jerusalem and with faith as a password through the perly gates, that we will be permitted to clasp hands with the Chief Health Officer of the Universe, the Teacher of teachers, and the Savior of mankind, and that He will place upon our brows a crown that will shine with greater brilliancy than his majesty, the King of Day, and that we may hear His sweet voice as it rings in our ears those tender words of "Welcome." "Well done thou good and faithful servants, enter thou into the joys of thy Lord."

A YEAR'S EXPERIENCE WITH SALVARSAN.*

By MAURICE S. DAVIS, Lexington.

Salvarsan, or "606" as it is commonly known, has been in use a little over a year. The length of time is hardly sufficient to warrant a statement in regard to its lasting effects in such a lurking disease as syphilis. However in his time the results obtained are of such a nature as to permit us to draw some conclusions as to its merits and as to what we might expect in the future. The mass of literature on the subject is most startling and from it one is made aware of one fact, namely: results from the use of this great chemical have been obtained.

A great deal of skepticism has existed against salvarsan, as is always the case in every new discovery, remedy or treatment. Especially has this antagonism been shown among our French and English writers, but as time passes and results show, the skeptics are becoming fewer and its converts more numerous. In this connection Wolbarst says, "There can be no denying the wonderful effects of salvarsan in syphilitic conditions. Undoubtedly experience is teaching us that a simple injection of salvarsan has the potency of a thorough course of mercury and iodide."

To treat syphilis properly and scientifically, we should take advantage of modern day advance. A serologic test should be made in every case of syphilis or suspected syphilis, before treatment and after, for only in this way can we judge of results, while unfortunately, like the greatest majority of all laboratory tests, it is not perfect; still it is the best

we have and therefore it should be used. It has been used in most of the cases with which the writer has had the last year's experience. Noguehi, (of the Rockefeller Institute) has recently announced a skin test for syphilis, similar to that now in use for tuberculosis, which he terms *metin*. His reports so far are only preliminary.²

Especially valuable is the blood test when it comes to a question of marriage among syphilitics, where to all outward appearances they are clear of the disease, and have been for the proper length of time. When the blood test is positive, you are that much more positive that you are doing the right thing in not permitting them to marry.

Heidingsford reports in those cases, which he could follow, after the use of salvarsan: 79 per cent. became positive after a negative blood reaction, 6 per cent. improved, 12 per cent. showed no change, and 3 per cent. retrogressed.³

Salvarsan was first administered as an injection into the deep muscles of the buttocks, an alkaline solution being used, 10 c.c. to each side. Fourteen cases were treated in this way.

Eight of these were the usual secondary cases in every day practice with the usual mucous lesions. These lesions cleared up in most of the cases in from eight to ten days.

Case No. 1, A. P., a negro man, which was shown at this society at its meeting in January, 1911, and reported by Dr. Stucky in the *MARCH JOURNAL*, was a case of tertiary syphilis, which enlarged the cervical glands marked oxena, and perforated septum was gone, with no swelling on either side of the nose all of which cleared rapidly. This case was seen about nine months after having received the injection and was still clear as far as the leucic condition is concerned.

Case 2, L. B., which was shown at the same time as case one: Infection about eight months previous had marked tertiary skin lesions over various portions of the body, leukoplakia. This man had been treated strenuously with deep injections of mercury, but responded only slowly to this form of treatment. Salvarsan was injected and he showed a decided improvement within ten days' time; about four months later he developed hemiplegia, and was seen in consultation with Dr. Clark, who concurred in the opinion that salvarsan had nothing to do with his condition.

Case 5. This was a female, referred for injection, married, with a gumma of the iris, associated iritis. The gumma disappeared within twenty-four hours after injection; the iritis cleared up in about two weeks' time.

Case 6, L. O., infant about eight months of age, was given a subcutaneous injection over

*Read before the Fayette County Medical Society.

the scapular region. The infant had no lesion showing at the time of injection, nor has it shown any since. The mother was given an intravenous injection at the same time.

The remaining five cases had nothing showing worth mention; all responded to treatment and showed rapid improvement.

Seventy-eight other cases were treated with salvarsan, given intravenously; 33 were primary cases, 19 were secondary; 16 were tertiary cases, and one congenital syphilis.

The primary and early secondary cases were injected immediately after a diagnosis was made either from the clinical evidence or laboratory findings. They present nothing of special interest other than that the eruption, where present, faded rapidly as did also the primary ulcer, if still showing. One case, a young lady with an extra genital chancre on the upper lip, the same swollen and painful, glands of the neck in a like condition; was seen two weeks after the appearance of the ulcer. Seriological test negative, no stain was made for spirocheta as bichloride had been used as an application to the lip. The young man whom this girl had kissed was examined and unmistakable evidence of syphilis was found and she was given an injection of salvarsan. The next day she said the lip and glands felt better and the swelling was perceptibly decreased. The case was seen to-day, just two weeks since the use of the medicine, and there remains only a slight crust and elevation at the lip to show where the chancre had been.

The later secondary cases present more of interest and show better what results can be derived from the use of salvarsan. Herewith is reported four cases in which the drug was used and the results obtained.

R., white, male, was seen by his home physician who told him that the lesion then showing on his penis was of an innocent nature. He did not improve under this man's care and he consulted an advertising quack who seemingly knew no more of his troubles than did the physician. When examined the man was found to be well advanced in the secondary stage of lues. Infection had taken place some time in the winter of 1910. The head of the penis and the fore skin were found ulcerated and swollen; the buccal cavity covered with mucous patches, enlarged and ulcerated tonsils, the vocal cords thickened; deglutition greatly interfered with; inside of the nose was very much ulcerated; cervical and inguinal glands enlarged. Twenty-four hours after receiving an injection of salvarsan this man showed change for the better; improvement was decided. In ten days time to all appearances he was entirely clear. He was seen on December 3, three months after the

time of receiving the injection and nothing showed on the patient.

T. K., was referred, had a small innocent looking sore back of the cornea which disappeared in a few days' time as did also the patient. He showed up again in about five weeks complaining of severe muscular pains all through the body, especially in the lumbar region. The thermometer showed a slight rise in temperature. He was put to bed and watched closely. Aspirin, etc., did nothing towards relieving his pains. After several days, a light eruption was observed on his body; also after close examination, some slight granular enlargement was found. A diagnosis of syphilis was made and salvarsan administered, relief being prompt, and in three or four days the patient left the hospital, free from all pain and able to resume his usual duties. It might be mentioned as a matter of interest that this man had on his chest a tinea versicolor covering a space about seven inches one way and three and a half the other, which also disappeared after the injection. This spot, so he said, had been present for several years. This man was seen about the last of January, almost five months after the injection and has had no trouble since. He refused further treatment.

T. C., white, male, contracted syphilis four or five years ago; was treated by local physicians; also had been to Hot Springs and received treatment there. Examination showed a large tertiary ulcer on the outer side of the left thigh. He was given an injection in July, 1911. Ulceration cleared in eight days time. He has had no trouble since, nor has he had any other treatment.

M. C., original infection eighteen years ago. Gives history of about one year's treatment with disappearance of all symptoms. Made a trip to Hot Springs about eighteen months ago and was under the care of Dr. Greenway for six or eight weeks. When seen about three weeks ago, presented the following symptoms with a clear history of syphilis: No active clinical symptoms other than patches on the tongue; had been feeling badly, losing weight, and complained of loss of appetite; pupils responded to light sluggishly; accommodation good; complained of girdle pain; parasthesia of soles; no Romberg symptoms, walked steadily with eyes closed, knee jerk slightly increased, no ankle clonus; no Babinski; complained of slight pains in leg. The man was highly nervous. There is quite a little doubt as to whether the pains in legs and girdle sensation and other parasthesia, were significant of tabs.

In the absence of other symptoms, however, salvarsan was administered and the patient was seen for the last time about a week following the administration and reported absence

of the girdle pain. Seemed not as nervous and said he was feeling better than he had in the past five years. These are about the average cases treated. Some were not so bad; others were worse. The results cited here are typical of the results secured in other cases. In every case treated there was improvement more or less marked and rapid; the cases showed general improvement as well, usually increasing in weight. Certainly mercury has also shown that it gives results, but not as rapidly and as easily, and this is a point which is to be sought in the treatment of syphilis. Lydston remarks, "In regard to the results obtained by salvarsan, I am free to say that while I have occasionally seen quite as remarkable benefits from intravenous injections of mercury, salvarsan is on the average much more trustworthy, far more speedy and definite in its action."

Heidingsfeldt and others give only the salvarsan and no other treatment, excepting in indicated cases. Frances Hagner gives an intravenous injection and follows within thirty days with a deep intramuscular, and this is followed with treatment as indicated. Some of our more conservative, however, are following the salvarsan treatment with mercury, as has been done in the cases here reported, where they would submit to its use. Mercury in some form or other has been advised in all cases.

Politzer says, "that it (salvarsan) is the most effective drug we possess for the symptomatic cure of the active lesions of the disease."⁵

This expresses the opinion of most of the later day writers on this subject. "Of one thing we may feel certain, namely, salvarsan has come to stay and that it will certainly play the principal role in the conquest of syphilis," is the statement of Wolbarst.⁶ All cases which we have treated with this have shown improvement. Especially rapid were those which had mucous lesions showing; next in rapidity to heal, were those with skin manifestations; and the glands were slowest to respond. Primary ulcers disappear in from 14 to 24 days, regardless of their duration. Salvarsan has demonstrated, at least to the satisfaction of most, that it is rapid, that it can do what mercury and iodide does, but in a shorter length of time.

The intravenous is the method of choice for the routine administration of salvarsan which method has been used by the writer since February 3, 1911, the solution being alkaline and given with Heidingsfeldt apparatus, usually into the median basilic vein of the left arm, inserting the needle through the skin into the lumen of the vein, where the same is superficial enough to permit of this, if not, the vein is exposed; .06 gm. is given to

the male and .05 gm. to the female; this is given in a 300 c.c. solution. Early a normal saline was used, but finding that it became cloudy it was changed to sterile distilled water, which is still used. This according to Corbus, makes an isotonic solution. These administrations were made in the hospital under every aseptic precaution. The patients were placed in a recumbent position and kept so for several hours following the use of the drug. In some of the earlier cases some of the solution was spilt in the tissues during the administration. When this did occur it was followed by slight pain and swelling in the region of injection. However this occurred only seldom and did not amount to much. In a half hour to three hours following the introduction of the salvarsan solution, the patient in most cases, experiences a chill, varying in severity, which is usually followed by nausea and vomiting, (the chill and vomiting is said, by some writers, to occur only where the water has not been freshly distilled and sterilized; this however, has not been our experience). The vomiting is followed by a rise in temperature, of a more or less high degree, having gone as high as 104 1-2 degrees F., in one case. It dropped to normal in about eight hours. However, some cases continued to run a temperature for several days after the injection.

In three cases we had persistent nausea following in the course of treatment; in one case this lasted for about four days; patient was unable to retain anything in the stomach during this time. In the other two cases the stomach continued to rebel against food for a week or more. Since this time they have had no trouble along this line. One case presented a herpes-zoster; another two cases had an arsenical eruption following the use of salvarsan.

In the deep injections, one case abscessed. In a large percentage of cases thus treated the buttocks became painful and swollen for several days following the injection. Some writers report as much as fifteen per cent of their cases to be abscess. Two cases which were injected into the muscles of the arm near the shoulder, by a physician whom it is pleasing to say lives outside of Lexington, the arm in both cases abscessed at the sight of injection and the tissues necrosed. Quite a little of the salvarsan was found deposited in the degenerated tissue when it was removed. One case, a male who had a marked polyuria (no albumen or sugar present) was benefitted in this respect for a while after injection of salvarsan. No kidney trouble has been observed to follow any of these cases, nor has there been discovered with the eye or ear symptoms following its administration. Keyes and others have discarded the use of iodipin as a vehicle

for a deep injection of salvarsan, on account of its after effects on the auditory canal.

Along this line the following from Bohm is of interest. "It was formerly thought that involvement of the auditory and optic nerves, reported in the German-European literature to follow the intramuscular injection of salvarsan, might be due to an arsenical neuritis, in which case there might have been idiosyncrasy on the part of the patient to arsenical preparations. This has since been disproved. Neuritis of cranial nerves, following such treatment, is merely coincidental and only a syphilitic inflammation of the nerve proper, with no connection whatever of the arsenic per se.

Ehrlich has referred to such a condition as neurorediven. Notwithstanding this fact there is to-day fallacious tradition among the profession, especially in unenlightened quarters, that salvarsan has produced and will produce blindness. The preponderance of evidence accumulated to-day disproves this statement.

Wechselmann's statistics of cases examined before the use of salvarsan show that the optic nerve was affected in three per cent. of his cases in the early stages. Wechselmann also reports a case of blindness after the use of salvarsan, in which case methyl alcohol was used as a solvent.

Contraindications to the use of the drug may be mentioned: alcoholism, organic nephritis, diabetes, ulcer of the stomach, organic heart diseases of any form, aneurysm, and other circulatory disturbances, etc. However, there have been cases reported where some of these contraindications have been disregarded and the medicine administered without harmful results.

Salvarsan has been administered in other diseases than lues, malaria, pellagra, sleeping sickness, stomatitis. In the latter some very gratifying results have been reported. Martin¹⁰ reports favorably on his experiences with salvarsan in pellagra, in the other maladies, the use of salvarsan has not been encouraged.

Every case of syphilis should be given the advantage of the drug. All primary cases, especially, should be subjected to its use, if for no other reason than that the symptoms of apparent or infectious lesions respond so readily to its use, and thereby lessening the danger of further dissemination of the disease.

No one can yet say positively how permanent or how lasting the results of salvarsan will be. We do know, however, that it does relieve the patient of the symptoms of syphilis and that the blood reaction becomes negative, frequently, after its use; therefore the writer believes that all patients infected with lues should be given the full advantage of this form of medication. He furthermore thinks

that all patients should receive a second dose of salvarsan, and that this should be followed by mercury and iodides and the usual anti-syphilitic treatment. Especially should this course be pursued until it is further demonstrated what salvarsan will do other than to clear the symptoms and give a negative serological reaction, but even as it stands the medicine should be used as a routine in the hands of one who has had experience in its use.

The writer wishes to express his thanks to Dr. S. B. Marks for his kindness and interest in these cases and also his appreciation to Dr. E. B. Bradley for his laboratory work in connection with the same. Appended will be found the report of Dr. Bradley's years' experience with the Noguichi serum reaction.

SUMMARY OF ONE HUNDRED AND SIXTY-SEVEN SERUM-REACTIONS BY THE NOGUICHI METHOD.

BY E. B. BRADLEY, LEXINGTON.

As a result of a year's work with the Noguichi test for syphilis, I find it to be as reliable as any laboratory test that we have for diagnosing disease. It is certainly as reliable as the Widal test for typhoid fever, and that is saying a good deal.

I have failed in one instance only to get a positive reaction where clinical evidence of the disease were present. I did not see this case but his doctor informed me that there was no question that it was a case of secondary syphilis. I have been struck with the high percentage of negative reactions in cases well treated with mercury, and with the difficulty with which a positive reaction is changed to a negative one with either mercury or salvarsan. One case that I have in mind is especially interesting; this patient had his primary over two years before consulting me and he had had what I considered thorough treatment, that is, he had been treated for these two years with mercury mostly hypodermically, and had had some treatment with iodide. His blood showed an absolutely positive reaction and salvarsan was given intramuscularly; this was some time in February, 1911; his blood, tested from time to time, always showed a positive reaction and he was given

hypodermics of gray oil for two or three months, these measures failing to change his blood reaction, he was given salvarsan again, this time intravenously, this also did not affect his Noguchi reaction and he was put on hypodermics of mercury again. After about twenty-four hypodermics, his blood has begun to clear up and his reaction while still positive is much less so than it has been before. I could not see that the salvarsan had the slightest effect on his blood-reaction, though it is very possible that it did so and was further helped by the mercury that he received. Other cases have cleared up after a single dose of salvarsan, though this is rather the exception than the rule.

THE USE OF SALVARSAN.*

By J. R. McGARY, Owensboro.

With the advent of "606" which Ehrlich has given to us as a new specific for syphilis, there has been poured into the medical world a flood of literature. The subject upon which the last word had apparently been spoken has again become a matter of speculation and investigation. Late methods of study have thrown new light upon the disease and at the same time rendered uncertain much that was apparently accepted as certain. The most important knowledge necessary at the present time for the proper use of salvarsan is how to make an early diagnosis.

The changes that are taking place during the incubation period of lues is biological rather than pathological. The spirillum known as the *trepanoma pallidum* is multiplying in numbers and preparing a base of supplies for the invasion of the host. At present we have no means of knowing when this army is being formed and we can only wait for the appearance of the chancre. Given the chancre, heretofore we have waited the silent and treacherous inundation of our defenses and have only begun fighting on the appearance of the eruption. This delay may mean the spiking of our guns.

If I am not mistaken there has been no opportunity offered nor any effort made to apply the Wasserman or Noguchi tests during the incubation period. As a rule a patient becomes alarmed only on the appearance of the initial sore. Now if in the incubation period there has been only a local multiplication of the spirilla and the host is not teeming with the spirochaetae, it becomes of paramount importance to be able to diagnose the chancre. The *trepanoma pallida* are found constantly in all chancres and in the regional glands. Neoggerath and Staehelin claim to have found them in the circulating blood. We are no longer doing our full duty towards these patients by sitting idly awaiting the secondary manifestations of the disease, if there is any special efficacy in early treatment. It seems a logical inference that if we have a specific the sooner it is used the more certain we may be of effecting a cure.

In nearly all cases the presence of the specific organism of syphilis can be readily demonstrated by obtaining serum from the chancre. The chancre should first be cleansed with soap and water to remove any pus or epithelial debris present, then slight irritation will cause bleeding. This should be wiped away with gauze and as soon as the serum appears two or three smears can be readily made. There are several stains that might be used for demonstrating the spirilla but the simplest and most rapid method of showing their presence is by the use of india ink, which does not stain bacteria, but leaves clear spaces which would immediately identify the spirilla. The possibility of error here lies in not distinguishing the *trepanoma* from other spirilla.

Cohn says, "The recognition of the spirochaeta pallida depends upon the observer's ability to differentiate it from other spirilla and to appreciate its distinct morphological characteristics. In size it varies in length from 7 to 21 microns (1-3000 to 1-1000 in.) It has the shape of an extremely slender thread, closely wound in a corkscrew form. They are observed to rotate on their long axis in either direction. The motion is very rapid but not necessarily accompanied by a change of position.

With the means of making a diagnosis in the primary stage at our command the successful treatment of the disease may be hoped for and by the proper use of salvarsan a speedy termination of the lesions accompanying syphilis may be expected. A complete sterilization of the body after one administration was Ehrlich's hope and the profession's disappointment. Nevertheless, we must not lose sight of the fact that "606" has been used in nearly every instance in the secondary and tertiary stages of the disease.

*Read before the Daviess County Medical Society.

The incision of the chancre in connection with enucleations of mercury has been advocated as efficient treatment. It seems correct to suppose from this that a drug which destroys the spirilla and heals the chancre in a few hours ought to be a complete and absolute cure at this stage of the disease.

My experience in the use of "606" in the primary stage extends to only one case. A young married woman manifested a chancre shortly after the appearance of the secondary symptoms in her husband. On account of the disease being evident in the husband I did not hesitate in making a diagnosis and the day following the discovery of the chancre administered intramuscularly in the gluteal region, .6 salvarsan put up after the formula of Loser. This consists on an alkaline solution diluted up to 10 c.c. in normal saline. The patient complained bitterly of the pain for about twenty minutes. The selective action of the arsenic for nerve tissue was clearly shown by the patient complaining of the pain radiating toward the heel. The injection was made as far from the sciatic nerve as was possible in this region. Four days after the administration of the "606" the chancre disappeared. There has never been any secondary eruption nor any other manifestation of the disease.

There is no special difference in treatment of the three stages of syphilis with "606" unless it be in the quantity of the drug administered. Heart lesions and arteriosclerosis are probable contraindications for its use. Blindness and deafness may follow the use of salvarsan. Arsenic has a selective action on nerve and epithelial tissue and consequently there may be an atrophy or degeneration of the optic and auditory nerves subsequent to the injection of "606". It rapidly heals specific ulcers, thus manifesting its effect on epithelial cells. The problem that presents for solution at present is, the best method of administering it and in what dosage.

One of the three methods of using "606" has not become popular—the subcutaneous. The choice is generally between the intramuscular and intravenous methods. The dose for intramuscular injections could either be larger or much smaller and often repeated. No matter whether the dose be large or small the pain following the injection will be severe. There is likewise danger of decomposition unless the salvarsan is quickly absorbed. Decomposition will invariably result in a slough. Personally have had no such experience with salvarsan and have always used the clear alkaline solution. The quantity of the drug used should be, I believe, .6 or .8 and not to be repeated in less than six weeks or .2 every week for four weeks. It is under-

stood that the injection should always be given with strict asepsis.

After six experiences with the intravenous method, one being a woman three months' pregnant, I feel inclined to advocate this method as far superior to the intramuscular. The introduction of the needle into the lumen of the vein is the most difficult part of the operation. By using a bayonet-formed needle with a three-way stop-cock we can demonstrate the position of the needle.

Salt solution is allowed to run freely into the vein before turning on the "606". In this way we can avoid infiltration of the tissues. Fastening a rubber tube around the arm until the veins swell facilitates the introduction of the needle. An alkaline solution diluted with salt solution up to 200 c.c. is a satisfactory solution for intravenous injection. The deaths reported due to the use of salvarsan have all followed the intravenous method of injection. This is the only reason for one hesitating to use this method. This way gives no pain and we have good reason to believe it to be more efficient. It can likewise be more often repeated.

Salvarsan is a wonderful drug. It will restore the paralyzed limbs due to gumma, the failing vision, the degeneration as found in our parasyphilis. As my experience with it extends, I become more certainly convinced that "606" if properly used, will cure syphilis.

When can we be sure of our patient's cure? There's the rub. Yet it is the end most anxiously desired. From recent reports the negative Wasserman does not seem to be of as much value as the positive reaction. This element of doubt will cause the profession to withhold judgment for many years as to the exact value of salvarsan. That it will cure paralysis and other effects of gummatous deposits renders it invaluable as a drug. If it would sterilize the tissues entirely removing or destroying the spirochaetae we can surely rid the earth of one of its greatest evils. This I believe possible if we can find a positive test for syphilis which will have no negative phase. This discovery will be greater than the remedy and may it come quick.

Massage of the Nerves.—Jaffe relates experimental research which demonstrated a markedly injurious action on nerve tissue from pressure such as is applied in the modern "pressure massage" treatment of neuralgia. Fifty-two experiments showed that the benefit in neuralgia is due to blocking of certain of the nerve fibres from degenerative processes. The centrifugal fibres seemed to suffer more than the centripetal.

SCARLET FEVER.*

By B. A. COCKRELL, Lexington.

I have a great deal of hesitancy in addressing you upon any subject pertaining to our profession, for I know that, no matter what subject I choose, those older than I are thoroughly familiar with it from their years of experience, as well as from their training, and that the ones nearer my own years are as conversant with it as I, because they, too, have but recently finished their school work and have had as much time since in which to receive experience.

I have chosen as my topic one of the contagious and infectious fevers, because most of my practice has been in those fields.

During my short stay among you I have been fortunate enough to have had about twenty cases of scarlet fever to treat and I shall attempt to tell you what I have learned from them.

Scarlet fever, or scarlatina—which comes from the old Italian, *scarlattina* or *scarlatina* meaning “red”—is an acute, epidemic, self-limited, exanthematous, contagious and infectious disease.

It is characterized by a scarlet flush spreading progressively from the neck over the body, reaching the hands last, ending, in from six to ten days, in desquamation; by a high temperature; by a rapid pulse, and by inflammation of the mucous membranes.

It is caused by a special microorganism which is as yet undetected but which is of very great vitality.

Edington noted eight kinds of bacteria in the blood and scales, one of which in the form of a rod or diplococcus, which, when introduced into animals, especially calves, produced a febrile affection with a cutaneous rash similar to that of scarlatina.

The bovine origin of scarlatina has been upheld in England for several years by both physicians and veterinarians and the contagion is supposed to result from ulceration of the udders and from the use of milk.

Whatever the agent of infection, it retains its infecting power for at least one year.

The desquamated epithelium is in all probability the bearer of the contagion, for during desquamation the disease is communicable to the greatest degree.

It is disseminated by the scales in the air, on food, clothing or on anything which may come into contact with the patient or the air which has been laden by the scales.

Sanne reported a case of a lady and her daughter living in Brittany receiving a letter from a friend living in Germany, in which the friend said she was convalescing from scarla-

tina and was peeling so freely that she had to stop every few minutes and shake the paper to get rid of the scales which fell on it.

The mother and daughter who received this letter were taken ill with scarlatina, the former died and the latter had a narrow escape from death.

The respiratory tract is the usual route of infection, but the digestive tract may also carry the infection.

However, this is still something of a moot point, as some claim the tonsils receive the virus.

Children are the most likely to contract the disease, but adults are subject to it. There are some cases which prove that the foetus may receive the contagion from the mother.

It is usually the most severe in the youngest cases, the mortality list showing 50 per cent. below 1 year, 11 per cent. between 1 and 2 years, and 2 per cent. from 2 to 10 years. In adults the mortality is about 1.5 per cent.

One attack usually confers immunity, but does not always do so.

The skin is the seat of the acute inflammation. The liver, spleen, stomach, kidneys, heart and muscles undergo granular changes.

Scarlatina predisposes to suppuration, a fact that is not surprising since we have learned that the streptococcus is inseparable from most scarlatina manifestations.

The incubation period is short, varying from 24 hours to 10 days.

There are rarely any constitutional symptoms between the time of infection and the onset of the disease.

The onset is sudden, there may or may not be a chill; vomiting is sometimes present, as are occasionally convulsions.

The temperature ranges from 100 degrees to 105 degrees, the pulse 100 to 150 beats per minute, both temperature and pulse being higher the younger the case.

There is pain in the throat and often the whole onset is typical of a case of acute tonsillitis.

At the end of 24 hours the scarlet rash appears on the neck and chest, spreading rapidly over the whole body. The eruption is not raised and disappears on pressure. It begins to fade as soon as it is complete, rarely ever lasting more than 5 or 6 days.

With the appearance of the eruption the throat symptoms are more pronounced, the tongue is first furred, later it becomes a typical “strawberry tongue”.

There may be headache, restlessness, delirium and loss of appetite. In a majority of the cases the bowels are constipated, in a few there is diarrhoea. The urine is scanty, highly colored and albuminous. Leukocytosis is present.

*Read before the Fayette County Medical Society.

About the time the eruption begins to fade the fever declines by lysis.

A simple uncomplicated case lasts from 3 to 14 days.

Now most of what I have read is what I have learned from text books, treatises, etc., I could write a small book on the same strain, as could each of you. What I have read you have, or can, read, so I shall confine my further efforts to my own cases. Of course it is only a limited experience but in one or two instances things rather unusual presented themselves and I hope they will prove interesting to you.

Of the twenty cases I have attended only four began with a chill, there was vomiting in six cases. Only twice did I encounter delirium.

Five of the cases gave every indication of tonsillitis on the first day, and not till the rash appeared was a positive diagnosis assured.

Three cases at no time had a temperature over 100 degrees, 101 was the limit for two more, 8 cases ranged from 102 to 103 degrees, 3 were from 103 to 104 degrees, while four went above 104 degrees, only one of which reached 105 degrees at any time.

One case had a pulse rate of 90 at the onset, which was the maximum rate throughout the whole course of the disease.

Two were around 100, 1 was steadily near 120, 3 were close to 130 all of the time, 5 ranged from 135 to 145 and 8 were over 150, one reaching 160.

The patients ranged in age from three and a half to thirteen years. The younger the patient, the higher the temperature and the pulse rate, and the longer the fever lasted.

In three cases, all of whom were over 10 years of age, the fever did not last but four days and was not higher than 101 degrees at any time. In 2 cases the fever left in five days, in 1 case it left in 8 days, in another in 9 days, and in another in 10 days. In 2 the fever lasted 11 days, in 3 it lasted 12 days, in 2, 13 days, 14 days in 1 case, 15 in 3 and 18 in 1.

The youngest patient was 3 1-2 years, she had a temperature of 105 degrees, pulse 160, respiration 32, was delirious, had a nephritic complication and the course of the fever lasted 15 days.

There were quite a number of complications that arose in the various cases. By complications, associated with scarlatina, I believe the correct way of putting it is "secondary infections".

Bronchial complications came up twice, 4 had a severe laryngitis and pharyngitis. Pronounced nephritis was present in 6 cases, otitis in 4, conjunctivitis in 3, and a cervical adenitis in 2 cases. In both of these last two

cases in which there was a cervical adenitis the patients gave a family history of tuberculosis.

In each case the abscess was slow in forming and gave every symptom of a cold abscess. They were opened, drained and treated accordingly and healed nicely and in a reasonable length of time.

Seven cases were in such condition that stimulation was necessary, in four of these strychnine sulphate gr. 1-60 was given every 6 hours. Atropine sulphate gr. 1-200 was used in one case and gave splendid results, it was discontinued after the third day, not being deemed necessary any longer. Whisky, drams 1-2, was given in conjunction with the strychnine in 3 cases and alone in 2 others.

It proved most satisfactory in every way and filled a place that no other medicine seemed able to occupy.

At the outset each patient was given a dose of calomel, ranging from 2 to 5 grains, according to the age of the patient. This was followed in 8 hours with a liberal dose of castor oil or saline.

In 2 cases where the fever was very obstinate, calomel, gr. 1-2, was given every night, with very beneficial results.

The fever was controlled by sponging with tap water whenever it went above 102 2-5 degrees. Tepid water was tried with a few cases but did not control the fever as did the tap water.

While tepid water would occasion a larger fall of the temperature within an hour after the bath had been given, it did not seem to have the lasting effect of the tap water. With tepid water the bath was necessary every 3 or 4 hours, while with the tap water the temperature could be controlled for from 5 to 7 hours.

Ice water was tried with two cases but produced too much of a shock so was discontinued.

In all cases a mouth wash was kept at hand and was used before the taking of either food or drink.

Dobel's solution was used in the severest throat cases and they were further benefited by an argyrol spray. In fact argyrol had a most satisfactory result in all the inflammations of the mucous membranes. It gave quick results in the eye cases.

For the bronchial cases elixir heroin and turpin hydrate controlled the cough and loosened up the phlegm.

In each case the urine was measured and the amount registered, color noted, also the odor. An examination was made of each patient's urine each day during the high fever and acute stage, as the fever declined the examinations were not made so often.

If albumin was present in a small degree lemonade was given in as large an amount as

the patient would drink—composed of lemon juice, grape sugar, cream of tartar and hot water—was given every four hours, or as often as the patient asked for a drink.

In one case the patient vomited this drink and it was discontinued and diuretin grs. 5 every four hours was given.

Each patient was put on a liquid diet at the onset of the disease and so kept till the fever had entirely gone. Milk, orange juice, and lime water were the chief articles of food.

In no case was diarrhoea present; on the other hand, practically every case was constipated during the whole course of the fever.

Cascara pills, castor oil and saline were used to keep the bowels open.

In only one case was there a pronounced sequellae, that was a case of nephritis which has not disappeared after fourteen months.

Middle ear complications left no permanent impression.

It is often the case, however, that there are serious results following the otitis from scarlatina. Many a case of mastoiditis can be traced back to a middle ear infection during scarlet fever.

Complete isolation and complete antiseptics are absolutely essential. The former was carried out as well as surroundings would permit and for the latter carbolic acid was used on all clothing, toys, dishes and in fact on every object that it was possible to handle.

In each case when the patient was removed from the room where the disease was first observable or where the patient was confined the room was disinfected with formaldehyde.

When in attendance upon one of these cases I left all removable garments in an outer room, or some other part of the house, and donned a cap and gown before going into the presence of the patient.

Upon leaving the patient I washed face and hands in bichloride or a 1 to 20 carbolic solution and in pure alcohol. After removing the cap and gown I washed again.

Moreover, it seems the only safe and sane thing to do to remain away from all children and maternity cases during your care of this, the most infectious and contagious of our diseases.

Auscultation Sign of Twin Pregnancy.—Le Lurier states that it is possible to train one's ear so that with the stethoscope one can distinguish the beat of the fetal heart when there are two fetuses. The sound is like that of a span of horses galloping; sometimes the feet fall together and it sounds as if there was only one horse, then the hoof-beats of both can be heard separately. This irregular double rhythm in the fetal heart beat is pathognomonic of a twin pregnancy. He ascribes the first description of the sign to Arnoux, 1908.

DIPHTHERIA.*

By WALLAS W. DURHAM, Crofton.

Diphtheria is an acute specific communicable disease due to the bacillus of Klebs and Loeffler, and let me say right here that the diagnosis of pseudo diphtheria and true diphtheria are the hardest thing that confronts the general practitioner in the up-to-date treatment of diphtheria. I am constrained to believe from my limited experience that all clinical cases of diphtheria are not diphtheria, while some cases that I formerly excluded from the role of diphtheria or failed to recognize as such, are diphtheria and no membrane present. Of all the cases I have had, ending fatally, save one, there was membrane visible, only a slight catarrhal inflammation of the pharynx, and in this one antitoxin was only procured and administered a few hours before death occurred.

As the clinical symptoms of diphtheria present wide variations it behooves us as guardians of the health of our clientele to be exceedingly cautious and with our perceptions on the alert when dealing with any pathological condition located within the favorite haunts of diphtheria, for we can ill afford as intelligent and well-meaning practitioners to examine a little fellow and leave a mild gargle and say to the parent, or family, that all will be well soon, to be called in a hurry the next day to find the patient choking and struggling for breath. The idea is to put the family on guard, post your pickets with full instructions for reporting the advance guards of the enemy and if you have at the time any misgivings use antitoxin and use it plentifully. In a great number of cases constitutional symptoms may be lacking, especially in nasal cases of young children. I have seen them when the parents suspected nothing of a graver nature than a cold in the head, though there had been a bloody purulent discharge for weeks.

The cases I believe most generally seen are of the tonsillar form and in dealing with this form beware of follicular tonsillitis as it may sometimes lead us astray, as symptoms of the two are so closely allied, we had better examine all cases of follicular tonsillitis at close intervals for the first 24 to 48 hours. The temperature ranges from 100 degrees to 103 degrees, patient saying that there is not much the matter, though the small specks of membrane may be seen to gradually coalesce or it may be that only a gray film, that grows into a fine white or yellowish patch that covers the tonsil, is the form. This form of diphtheria is the kind that generally causes the epidemics, as parents are loath to keep chil-

*Read before the Christian County Medical Society.

dren in quarantine when the illness causes no more inconvenience than this.

In the severe cases the onset is usually gradual, a few days of indisposition, with or without soreness of the throat, or as happens sometimes, the first symptoms to be noticed is a chill or severe aching and a high temperature, in such cases, once or twice, I have suspected mumps from the enlargement of the cervical lymph glands, the mouth being opened painfully and face slightly reddened, patient is restless, sick stomach, anorexia, hard breathing, instead of keeping upon the boundary of the tonsils membrane spreads rapidly to the uvula, fauces and pharynx, and the more rapidly it invests these the harder you've got to fight, patient always complains of excessive mucus in the mouth, painful expectorations and difficulty in breathing through the nose, patient wants to sit up, can breathe better, tongue is dry and sore, breath offensive, and in some cases fluids will be regurgitated through the nose; where intense toxemia is present, we have the prostration and stupor accompanied with the restlessness, pulse weak and thready, when the disease spreads to the larynx we have hoarseness and the croup cough, after one has once seen the facial expression and the maneuvers of a child suffering from this form of diphtheria it can not be mistaken and in my practice laryngeal is the most dreadful of all forms, experience has taught me that whenever in doubt about the diagnosis to use antitoxin, sometimes the cases we least suspect prove an undoing and in this day of good weapons to fight with, let's take opportunity by the forelock and fight for our little fellows mightily.

We have saved more lives in the last ten years by the use of antitoxin than all of the peace congresses will save from violent death in the next fifty years.

PNEUMONIA.*

By J. D. ROBERTS, Stanley.

Pneumonia is a wide-spread disease and found in all parts of the world. We have different kinds of pneumonia; namely, croupous, catarrhal and metastatic croupous pneumonia sometimes called lobar pneumonia or lung fever.

The development of croupous pneumonia is dependant upon many causes, some of which we do not know. Some cases are those external to the body, which produce a condition in the individual favorable to the growth of the specific germ and internal causes which exert similar influence, such as heat, cold and exposure to dust and bad air and a debilitated system of the individual.

Croupous pneumonia is a disease particularly apt to attack those advanced in years. Such patients seeming to have little resistance to its attack. This inability to resist the infection depends upon at least two causes, viz: a feeble heart muscle, which cannot meet the circulatory demand of the disease or resist the depressant effect of its toxins. A diseased kidney, or kidneys, impaired in function, whereby toxic material cannot be speedily eliminated, and the general result of which the vital resistance of all the tissues are diminished, so that not only the micrococcus lanceolatus is permitted full sway, but the patient is also placed in a favorable condition for the growth of other infecting micro-organisms, which aid in producing a fatal issue.

It is because of these factors that pneumonia so frequently attacks those in ill health, or who are suffering primarily from some other malady,

In studying croupous pneumonia it must not be forgotten that the disease, at least in some cases, is a general infection with the micrococcus lanceolatus or pneumococci. The morbid changes being modified in the lungs as is typhoid fever in Peyer's patches. The pneumococci are found in the blood during the progress of this disease, with great frequency. While it is true, as already stated, that croupous pneumonia is in its typical form due to the pneumococcus, it is also a fact that lobar or consolidation of the vesicular portion of the lobe or lobes may arise from infection from other microorganisms, but such an accordance is, however, rare. The non-specific infection resulting usually in abortive changes or running a course at variance with the true infection.

PRIMARY STAGE.

The first changes taking place in the lung in croupous pneumonia is a hyperaemia of the intervesicular tissue of the lobe or lobes about to be consolidated. The congestion rapidly becomes more marked and is accompanied by the exudation, into the air cells, containing red blood cells with serum and fibrinous material, which speedily becomes solidified, so that the part of the lung which is affected may, in the course of a few hours, be devoid of air and impervious to its passage, except in those bronchial tubes of some size.

In the stage of red hepatization the lung is enlarged and red from the amount of exudate and the red blood cells. The exudate in many cases are extremely large as shown by the fact that a lung may increase in size and weigh seven or eight pounds. At the stage of gray hepatization the acute inflammation has passed the system is trying to rid itself of the waste products caused by the disease, which is accomplished by the cells undergoing

*Read before the Daviess County Medical Society.

a fatty degeneration and granular changes, with fibrin softening. During resolution the exudate is gotten rid of by absorption and expectoration, finally air cells are freed from the exudate which has been filling them. The epithelial lining then is reproduced and recovery results. In some cases the normal process of resolution is not followed and in its place organization of the material which takes place to some degree, now connective tissue is proliferated into the air vesicles from their walls, and fibrinous bands and blood vessels extend throughout the part of the lung affected in this way simultaneously a similar growth takes place in the interstitial tissue and so the lung gradually becomes consolidated by over growth of fibrinous tissue. The period of incubation is from forty-eight to seventy-two hours. The variance of attack of pneumonia depend not only upon the virulence of the infecting germ and the susceptibility of the patient, but upon his habits and his surroundings, age and his general health. If the patient is feeble it sometimes happens that the onset is insidious and no pain felt. This is especially apt to be true when the disease follows alcoholism, or renal disease; the temperature takes rise after or during a chill to 105 or 106 and remains throughout the disease. The variation of morning and evening temperature not more than a degree in difference.

The treatment of croupous pneumonia consists in keeping the patient comfortable, plenty of fresh air and sunshine with as few drugs as we can possibly use. We use the following drugs according to conditions and complications, if there be any, quinine sulphate, Dover's powder, tr. aconite, tr. belladonna, tr. digitalis and strychnine use these according to age and condition with hot and cold sponging, give patient a light, soft, nutritious diet, easy to digest.

Lobular pneumonia is an acute infection of the small bronchials and the tissue immediately surrounding them and primarily involves the lobules rather than lobes as does the croupous type of pulmonary consolidation.

No single or specific organism is the cause of broncho-pneumonia, but due to infection of the bronchi and adjacent tissue by many pathogenic germs, but is principally caused by the streptococcus or staphylococcus, also the Klebs-Loeffler bacillus; also this disease seems to follow measles, whooping cough and diphtheria, old age and debility are predisposing causes. This form of pneumonia, at least in its earlier stage, occurs in patches and the exudate contains less fibrin than in croupous pneumonia. The exudate of broncho pneumonia undergoes resolution as do most inflammatory exudates.

When a child is attacked with broncho-

pneumonia there is usually a chill at onset which varies greatly with severity, as rise of temperature, increase in respiration, the irregular pulse of pneumonia is of evil import, the cough is fairly constant, which sometimes produces pain, increased respiration is for protection of the affected side.

Auscultation will probably reveal some fine rales in some of the finer bronchial tubes with exaggerated inspiration and somewhat prolonged expiration. We may also have dyspnoea or cyanosis or both. Very speedily too much carbonic acid gas accumulates in the blood and benumbs the child so that it may be motionless except rapid respiration, which are required to maintain life.

The duration of broncho pneumonia varies greatly with the condition at the time of the onset of the disease. The prognosis of broncho pneumonia varies greatly with the underlying causes and the age of the patient. In very young infants the prognosis is exceedingly fatal. In the treatment of broncho pneumonia give the patient plenty of fresh air and sunshine if possible.

No medicines which interfere with digestion should be given with the food.

For external applications use turpentine and sweet oil, or turpentine, coal oil and lard with quinine sulphate. Give some anodyne to maintain quietude, also hot baths, then wrap in hot blanket before drying patient. For a stimulant use carbonate of ammonia.

In some of the critical periods we use Hoffman's anodyne, also in others strychnine. If the bronchial secretion is considerable, particularly in the suffocative form, a critical period may be overcome by small doses of atropine. The use of antipyretics are to be condemned in these cases. To control temperature use hot or cold baths, as the condition may demand. During the acute stage there is resolution if the secretions are profuse, use small doses of chloride of ammonia with fluidextract licorice in water.

The younger the child the less chance there is to free the lungs of exudate by coughing, and care should be taken not to hinder nature's work, only aid to free the exudate, aid digestion, which is of great importance to maintain the health of the child. Keep up good elimination by all the natural channels possible.

Give you treatment heroically while they are able to take and retain for when they become so devitalized as to reject any and all treatment for a recovery this being my motto, give while able to take and retain.

CASE REPORTS.*

By E. J. BROWN, Stanford.

As I was permitted to select the topic for paper at this meeting we will report a few cases and pathological specimens.

CASE I.

We present this young man to you, for whom we have operated for mastoiditis. He is 19 years of age, father and mother both living, and his history is negative except diseases of childhood, and pneumonia, which preceded this infection of the mastoid cells. He called at office on February 3rd, presenting the usual symptoms of beginning pneumonia. We were called next morning to see him and found him with unilateral pneumonia. He reached crisis on February 12th, and began to clear up, when on February 17th we were called to see him and found him suffering intensely from infection of left mastoid. Temperature about 101 and pulse 90. Tenderness, redness and swelling was marked over mastoid region. We did not make blood count in this case, yet it should be done in all these cases. The diagnosis was positive. We realized the importance of immediate operation, but he was yet weak from pneumonia and we feared the effects of the anesthetic. On February 24th, Dr. Phillips and Dr. Harmon assisting, we opened up the mastoid with chisel and drill and found large quantity of pus. We did no damage to the nerve or sinus. Packed with iodoform gauze. The after treatment consisted of gentle irrigation and light packing. You observe the scar, which shows but little depression. The only special feature in this case, it was sequel of pneumonia and had we made microscopical examination, which we should have done, no doubt would have found pneumococcus infection. As you see he is regaining flesh and strength.

CASE II.

We show you section of fibroid uterus. Mrs. R., age 35 years, housekeeper, mother of two children. No history referable to the pelvic organs except heavy bearing down sensation when on feet too long. Was called to see her on October 26th, 1911. Found her bleeding from uterus and found she had aborted, from history and size of foetus, about third month. In removing debris and clots, I found uterus of unusual size. I at once made diagnosis of fibroid tumor.

Dr. J. F. Peyton saw this case on the following day with me and confirmed diagnosis. We realized the peril in the future, she would be subjected and advised operation, notwithstanding she had just aborted, and added

some to the risk. The request was granted. Having procured a nurse, and making all necessary preparations, on October 29th, assisted by Drs. Peyton, Phillips and Craig, we did a supra-vaginal hysterectomy. She made splendid recovery and weighs more now than ever before in her life. Writers, possibly fail to emphasize, among the other conditions arising in these cases, the danger in habitual abortion, produced by fibroids. She is now secure against the many dangers incident to life, in women of her age with a fibroid. Had she been older and reaching menopause, conservation might have been considered. Injury to the bladder and ureters in hysterectomy, and in fact all pelvic work, is *bête noir*, to the man who does limited amount of abdominal work. I have a method in those cases, to relieve my mind of that dread which follows for several hours after operation as to whether the urinary tract is damaged or not. We give a few tablets of methylene blue for two or three days before operation and if any injury is done the color shows at once on the clean sponged surface. It also saves smelling and tasting of the fluids which appear from time to time in the field of operation. Hemostasis is the most important point in these cases and the most difficult to procure. Avoid over-stimulation with strychnia, adrenalin, vomiting or any and all the things that stimulate the heart and raises blood pressure. Secondary hemorrhage is more dangerous in country work, because of the inaccessibility of the physician. The symptoms of hemorrhage are too well known to all to require comment. Nurses should be thoroughly drilled in this particular phase of surgical work.

CASE III.

The next case we report is a case of hepaticotony. We hoped to have patient here today but she lives in the country, and her physical condition is not such yet as to have her ride over rough pike. The patient, female, age 56 years, mother of eleven children, no previous illness, except some form of nerve affection about 15 years ago. Never had typhoid. Her present illness dates back seven or eight years, having been treated often for stomach trouble. I was called to see her on February 6th, and found her with pain and tenderness over gall-bladder. Murphy's perpendicular percussion elicited quite severe pain. She had never been jaundiced. I was called to see her again in two or three days, suffering more and jaundiced. We spoke to her about surgery, but did not insist, and told her we would palliate her as much as possible, and operate if it came to emergency. Now this is the way to win over country patients to surgery. Every one of them have in store, for reply when you urge surgery, some cases

*Read before the Lincoln County Medical Society.

where the patient was told by some surgeon that they were bound to die if not operated. They will tell you operation was refused and the patient is well to-day. She went along gradually improving, symptomatically, until March 1st, when she began to feel much better, and thought she would soon be well. On March — she had an acute attack, followed with marked jaundice. We again called to see her and she willingly consented to operation. We secured a nurse, prepared patient, and on the next morning, assisted by Drs. Peyton and Phillips, we did hepaticotomy. The Kocher incision was made, the gall-bladder was empty, contracted, and adhered to underlying structures. With gauze pads we protected cavity and carefully loosened adhesions, until we could palpate ducts. We found the cystic and common duct clear, but large stone in middle third of hepatic duct. I should have stated that the patient had no elevation of temperature or pulse before operation. The contraction of the gall-bladder was evidently due to its non-functionating. The stone could not be milked into the common duct or back through the cystic duct. We picked up the duct between thumb and finger and incised directly over the stone. After removing the stone, which we herewith present, it was as large as a sparrow egg before it was crushed. We stitched over incision with fine gut and passed rubber tube, wrapped with gauze down to incised duct and closed in usual way. The jaundice began to clear up at once and she had done well. Digestion is fair and she is able to walk about the room. It was many years after Sim's unsuccessful, and Tait's successful, cholecystotomy, before Kocher did hepaticotomy. It is the rarest operation of the gall-bladder system. We followed as near as possible, the technique of Moynihan, of Leeds, England. Hemorrhage, which is always dreaded in jaundiced patients, gave us no trouble, yet we took no precaution, as is advised by Mayo Robson, by administering calcium chloride for a few days previous to operation.

CASE IV.

Prostatectomy. Mr. D., age 77 years. Had been troubled for five years, frequent desire to urinate with difficulty to start urine. The symptoms increased all the time until we saw him on January 12th. He came to our office and demanded relief, life was not worth living in his present condition. Rectal examination revealed a large prostate, as we here present to you for inspection, weighing over 16 grammes. Urine examination showed pus, mucus, and alkalin in reaction. Physical examination showed a man who had formerly been very strong, but long continued sepsis had sapped his former vitality. He was a

very sick man and miserable in his own eyes. We told him the death rate was high in those cases. He said it made no difference as he could not live in this condition, had no special desire to. We had him go to bed, placed him on diet and urinary antiseptic, washed out the bladder frequently and soon had him in fair condition. On January 19th, assisted by Drs. Peyton, Phillips and Craig we did suprapubic prostatectomy. The lobes were large and incision of the capsule was made with scissors, they peeled out easily. Hemorrhage light. Drainage from start was perfect. Used sound on third day. Drainage opening closed in three weeks. Formerly was up and down a dozen or more times a night with great pain. Now he gets up only once during the night and with perfect comfort. He has regained much of his former vitality and looks to be many years younger than he is. The preliminary preparation has much to do with results in this class of cases. The extremes of life should not be deprived of great good which may be given them by timely surgery. I show to you an old photograph of a boy who is now a young man, on which I did intestinal resection upon the day he was 35 days old. It was a case of congenital hernia which became strangulated and gangrene was the result. We would not have operated if we had known it was gangrened, but we found nothing else to do when we found such condition existing. We did end to end anastomosis, and the little fellow did well from the start. This is the youngest case of resection we have been able to find on record. So let's be generous and give all a chance for life and comfort.

As to the after-treatment of these abdominal cases, I know of nothing better than that given in an article in the March number of our STATE JOURNAL, written by Dr. L. S. McMurry. The old method of drastic purgation, long starvation, withholding of fluids before and after operations, seems to-day like a relic of barbarism. We must be careful or the pendulum will swing too far in the other direction. That article states that water given after operation, though vomited, makes no difference. If the patient is just from the operating table, and not retching and water produces retching, in many cases of abdominal work, it would be far better to withhold the water. For example in all the ostomies of the stomach and intestines, with the tissue like structures and delicate sutures a single retch may seal the destiny of that patient, before adhesive inflammation has had time to make sufficient repair, to withhold the strain produced by the contraction of the voluntary and involuntary abdominal muscles. As we said before in this paper, in speaking of secondary hemorrhage, anything that stimulates the heart or rises blood-pressure may liberate

a struggling vessel or release a poorly tied ligature. The discussion of that paper deals, possibly, too lightly with drainage. In septic cases the modern technique has never lessened the necessity for drainage, and if done at all, should be done effectually. Tait said, "When in doubt drain." The question of irrigation, in pus cases, was discussed also. Is not the patient better off with sterile water in the belly, than when it is full of ill-smelling, germ-laden pus? By not using any complicated apparatus, for irrigation which we will grant might produce some traumatism, but make triviale speculum with three fingers and gently flow in pure water until it returns clear, what results could come of it except for good? It was said in the discussion of that paper that you destroy the leucocytes. We never knew a phagocyte ever did anything after it passed out into the free cavity into a pool of pus except to make more pus by being converted into pus. The "Fowler" position is an acknowledgement of imperfect surgery. The cases which need drainage, are already very sick and often anemic when they go on the table, then they get the surgical shock, anesthetic shock and the psychical shock, hence to bring them around after all this they need blood in the brain, "anti-Fowler position." If the work was as complete and the toilet as perfect as was done by the lamented Joseph Price, and is now done by his successor, Dr. J. W. Kennedy, the "Fowler position" would exist only in history. Puncture surgery and imperfect surgery have created the demand for the Fowler position. Well, but hold on, they say; our patients get well. "They breathe" but they are miserable from the effects of inflammatory products and adhesions. They are the harvest for post-operative work.

Diagnostic Intradermal Reaction in Syphilis.

Fontana has experimented with various substances, sodium glycolate, lecithin, etc., injecting them into the skin by the intradermal technique. None proved reliable for eliciting a specific reaction except a glycerin extract of syphilitic livers or superficial lesions. Scraps of a condylo-ma lata, swarming with spirochetes, were triturated with five times their weight of neutral glycerin and after standing for ten days in a cool place the fluid was filtered and distributed in vials fused and kept at 56° C. (132.8° F.) for an hour on three successive days and then set aside in a cool place again for two months when the "syphilin" was ready for use. In sixty-seven tests, the syphilin gave positive findings in 47.5 per cent. of the cases while the Wasserman reaction was positive in 85 per cent.; in the primary and tertiary phases the two reactions constantly paralleled each other. The method is thus not without value and when the technique is further perfected may prove important.

NEWS ITEMS AND COMMENTS

BOYD—Dr. Farris L. Allen, of Ashland, visited the State Board laboratories and was much pleased with them.

CAMPBELL-KENTON—Free Dispensary opened recently at 1014 Russell Street, for tuberculous patients.

CAMPBELL-KENTON—Dr. T. J. Glenn was elected City Bacteriologist by the Board of Health at our last meeting.

WARREN—Dr. E. N. Hall and Dr. J. H. Blackburn are the happy owners of a new 30 horse-power Buick each.

BOONE—Dr. L. C. Hafer and family, of Florence, have returned from Florida, where they spent the winter.

HARRISON—Dr. H. T. Smiser returned on May 1st from Arizona, where he spent the winter. The doctor is much improved in health.

GARRARD—Dr. J. A. Amon, Lancaster, has a new 30 horse-power Buick. All our physicians are using or contemplating using machines.

WARREN—Miss Laurie Clay, of Lexington, the noted suffrage platform lecturer, visited the laboratories of the State Board of Health last month.

GRAVES—Dr. Lilian H. South, State Bacteriologist, gave an interesting lecture on "Hookworm," at Mayfield, and had quite a large audience.

Harlan—Pellagra has again invaded Harlan county and several cases of a severe type have been reported in the immediate vicinity of the town of Harlan.

ALLEN—We are sorry to learn of the death of Mrs. W. A. Callis, wife of Dr. Callis, of Scottsville, and extend our deepest sympathy to him in this great bereavement.

OWEN—Dr. Maurice Bell, Monterey, President of the Owen County Medical Society, has returned to his home after undergoing an operation for inguinal hernia, at Norton Infirmary, Louisville.

SIMPSON—Dr. M. M. Moss, of Franklin, has returned from New York City, where he has been doing special work in Eye, Ear, Nose and Throat. After July 1st, he will be lo-

ated in Bowling Green for the practice of his profession.

Onio—Dr. Palestine Willis, of Cronwell, has moved to Beaver Dam, Ky. Dr. A. B. Riley and Dr. E. B. Pendleton, Hartford, have just recently recovered from smallpox. There are several cases of smallpox in Hartford and Centertown neighborhoods.

CAMPBELL-KENTON—The foundation for the New Elizabeth Hospital is about completed. The hospital will be modern and contain 300 beds. There will be five separate buildings which will occupy one whole square. The buildings will be four stories in height and will cost, when finished, \$250,000. It is being built by the Sisters of the Poor of St. Francis.

MAGOFFIN—Dr. Freeling Taylor, of Lykins, Magoffin County, who went to California a short time ago for his health, was operated on in that State for some kind of kidney trouble from which operation he never rallied. He graduated from the Kentucky School of Medicine, at Louisville, in 1889; was a successful physician and his place will be hard to fill in this county. He was one of the best posted physicians in the mountains in a general way.

IN MEMORIAM

DR. H. C. DUVAL.

Dr. H. C. Duvall, aged 68 years, died at his home, Millwood, on April, 1912, of organic heart disease. Dr. Duvall was one of the oldest and most prominent practitioners in Grayson county, having practiced his profession actively for forty-seven years. At the time he began practicing there was not a clinical thermometer or an hypodermic syringe in the county. He graduated in 1875 at the old University of Louisville. He located first at Big Clifty, Ky., and was for years associated with the late Dr. Terry, a profound friendship soon existed between him and Dr. Terry which lasted throughout their lives.

He was active and energetic in his practice and successful from the start. He held many positions of honor and trust during his career, being at his death the President of the Grayson County Medical Society and was always an active member of the society, while his health in late years was precarious, yet he rarely failed to attend the regular meetings. He was for several years surgeon for the I. C. R. R., at Big Clifty, Ky., and on his removal to Millwood was appointed surgeon for the company there. He was for several years health officer and member of the Board of Health of Grayson County, and was always active and efficient in the discharge of

his duties and for the cementing and upbuilding of the medical profession.

Religiously he was a member of the Baptist church and moderator of the church at the time of his death. He was greatly beloved by all who knew him, being a congenial spirit and fine story teller, he had a great fund of humorous anecdotes and experiences which at all times enabled him to entertain his hearers and made his presence a welcome one at all gatherings.

Lastly it can be said of him that his life was not in vain. His life was clean and worthy of imitation, his career was eventful. He accomplished much in the short space of time that was allotted to him to live and we hope and believe that the good that he has done will like "The bread cast on the waters return to him after many days."

RESOLUTIONS.

Whereas, the Great Creator in his wisdom has seen fit to remove from our midst a worthy brother practitioner, President of our County Medical Society and member of our State and National Associations, in the person of Dr. H. C. Duvall, of Millwood, Ky.

Be it resolved by the Grayson County Medical Society:

1st. That our County, State and National Medical Associations have lost a most honorable, active and earnest member, and we deplore the fact that his voice and presence in our Society is forever ended.

2nd. That we extend to his family our most sincere sympathy in their great bereavement, believing as we do they have lost a kind and indulgent father and husband and the community one of its best and most substantial citizens.

3rd. That a copy of these resolutions be handed to the bereaved family, and a copy be sent to the Leitchfield Gazette and Kentucky State Medical Journal for publication.

B. C. WILSON,

W. S. CLARKE,

J. W. CONKLIN,

Committee.

COUNTY SOCIETY REPORTS

Graves—The Graves County Medical Society met at the court house May 1, 1912, at 10 o'clock a. m. The president being absent, on motion of Dr. H. H. Hunt, Dr. John G. Puryear was elected chairman pro tem.

Minutes of last meeting were read, approved and adopted.

The applications of Dr. Richard Keys and Dr. M. W. Hurt for membership were acted upon favorably and they were unanimously elected to membership of the Graves County Medical Society.

The following officers were elected for the ensuing year: President, John G. Puryear, May-

field; First Vice President, M. W. Rozzell, Mayfield; Second Vice President, W. B. Stokes, Farmington; Secretary-Treasurer, Richard Keys, Mayfield.

A vote of thanks was unanimously extended to H. H. Hunt, the retiring secretary and treasurer for his long and efficient services as such.

E. G. Thomas, of Marshall county, made a short talk on surgery with report of cases.

J. G. Puryear made an interesting talk on vomiting in pregnancy with report of case, followed by short discussion by Drs. Fuller and Hunt.

B. F. Green made a talk on membranous croup with report of cases.

E. G. Thomas made an interesting talk on Marshall County Medical Society.

W. H. Letcher brought a patient before the society for examination and it was decided to be a case of gall stones and proper treatment was recommended.

There being some misunderstanding as to the classification of insurance companies doing industrial business and fees to be charged for examination in same, the subject was brought before the society for discussion and settlement on motion of Dr. G. T. Fuller, seconded by Dr. J. H. Shelton.

Various motions and amendments were put before the society and after a very heated discussion, Dr. Hunt upholding the industrial side of the question, they were all tabled and it was decided to refer to the State society as to whether they accept the fees as is adopted at present by the industrial companies.

The noon hour having been reached the society adjourned until 2 o'clock p. m. Society was called to order by the President.

J. H. Shelton spoke on "Are Doctors Going to Charge Morphine Habitués for Prescriptions?" discussed by Drs. Richmond, Stevens, Fuller and Wesson.

J. C. Sullivan spoke on "Hio-Colitis," discussed by W. J. Shelton and Dr. Wesson.

W. W. Richmond spoke on "Hookworm."

Dr. Richmond was followed by Dr. Lillian South, of Bowling Green, State Bacteriologist, who gave a highly interesting talk on technique for collecting specimens and making examination for hookworm, tuberculosis, typhoid fever, etc.

The society then adjourned to meet at the court house at 8 o'clock p. m., and Dr. South delivered her famous lecture on hookworm, typhoid, tuberculosis, etc., illustrated with stereopticon views. A large crowd was present, men, women and children, and it was pronounced by all to be highly entertaining as well as instructive and educational and the Graves County Medical Society extends to Dr. South its thanks and appreciation for the excellent talk and will gladly welcome her into our midst again.

W. W. Richmond, of Clinton, closed with quite an instructive talk on hygiene.

RICHARD KEYS, Secretary.

Ohio—The Ohio County Medical Society met in the office of Dr. S. D. Taylor, Beaver Dam, Thursday afternoon, May 2nd, at 1:30, with the following members present: S. D. Taylor, J. W. Taylor, E. W. Forl, J. O. McKinney and Oscar Allen, Dr. George Mitchell visitor.

The meeting was called to order by J. W. Taylor, the president; minutes of last meeting were read and approved. Dr. J. A. Duff's application was acted upon resulting in his being unanimously elected to membership.

J. W. Taylor presented a case of sprain of the sacro-iliac synchondrosis.

E. W. Ford reported a case of supposed erythema nodosum.

J. O. McKinney reported a case of dermatitis resembling the eruption seen in pellagra.

E. W. Ford gave us some of the more important things with which he was impressed while at the Chicago Polyclinic. Among which he mentioned the universal use of rubber gloves in all surgical operations; ether as an anesthetic; Iodine as a disinfectant; Scarlet red salve in the treatment of ulcers; A gauze mask for the face and a paste board splint for the elbow in treating facial eczema among children. The importance of obtaining the blood pressure in many diseases. The importance of an early diagnosis of tuberculosis and its treatment with tuberculin. The importance of absolute quiet in ulcer of the stomach and raising the percentage of haemoglobin above 80 per cent.

Oscar Allen read a paper on "Hio-Colitis."

Program for next meeting: **J. W. Taylor**, "Arteriosclerosis"; **Willard Lake**, "Gastro-enteritis."

Adjourned to meet Thursday, June 6th, 1:30 P. M.

OSCAR ALLEN, Secretary.

Pendleton—The Pendleton County Medical Society met at the Day House in Falmouth, with the following members present: J. H. Barbour, P. N. Blackerly, O. W. Brown, J. A. Caldwell, N. B. Chipman, H. C. Clark, N. H. Ellis, S. M. Hopkins, W. A. McKeeney, John E. Wilson, J. Ed Wilson, K. B. Woolery, W. H. Yelton and J. F. Daugherty. The meeting was called to order with the President in the chair, and after roll call and reading of the journal of the previous meeting, we proceeded to the business of the day, after a few reports of clinical cases.

There being no essayist ready with papers, we entered into a general discussion of matters pertaining to the welfare of the society, after which we adjourned.

April 10, 1912.

W. A. McKENNEY, Secretary.

Pendleton—The Pendleton County Medical Society met at Falmouth, with the following members present: J. H. Barbour, Beckett, Blackerby, Brown, Clark, Dagherty, Ellis, Hopkins, Kendall, McKenney, Nichols, John E. Wilson, J. Ed Wilson, Woolery and after roll call and reading of the journal, we proceeded to the business of the day. Under new business Dr. Clark made a motion that the secretary write each of our United States Senators and request them to support the Owen Bill.

We had some very good reports of clinical cases, after which we adjourned until afternoon, when the reading of papers and their discussion was taken up.

C. H. Kendall read a splendid paper on "Fatty Heart," which was discussed by several members present.

John E. Wilson then discussed "Acute and Chronic Myocarditis," in a very thorough and comprehensive manner, as he is very capable of doing. This led to a general discussion of the subject and some very rare and interesting experiences were reported, which was highly appreciated by all.

This closed the meeting for the day and all left feeling that they had been greatly benefited by the meeting.

W. A. McKENNEY, Secretary.

Simpson—The regular meeting of the Simpson County Medical Society was held on May 7, 1912, in Franklin with a good attendance.

M. M. Moss brought up for discussion the new treatment of goitre, namely that by ligation of the thyroid arteries. During the lengthy discussion several cases of cure or partial cure were reported by other methods of treatment.

There were several case reports by other members present and Dr. Venable asked the members to report any cases of suspected hookworm and send in samples of feces for examination. Thus far this disease has not been found in our county.

F. E. McCann will be essayist at the June meeting with a paper on "Autointoxication."

The Simpson County Medical Society will entertain the Tri-County Medical Society in Franklin in July.

F. E. McCANN, Assistant Secretary.

Warren—The Warren County Medical Society entertained the Tri-County Medical Society April 9, 1912. An elegant dinner was served at the Morehead Cafe. Many interesting papers were read. The regular proceedings will be reported by the secretary of the society.

L. H. SOUTH, Secretary.

Warren—The regular meeting of the Warren County Medical Society was held in the City Hall, Wednesday, May 8, at 1 P. M., with the following doctors present: T. W. Stone, F. D.

Cartwright, D. B. Stone, Huddle, Souther, Hall, South, Blackburn, W. C. Strother, Wm. Drake, Helm, London, H. P. Cartwright, Abernathy.

J. H. Souther reported a case as follows: A young lady of neurotic temperament, had a "fit" about three years ago, thought at the time to be due to eating too much hog meat. Several days ago the same symptoms recurred, was unconscious, muscles of the hands contracted, hallucinations, delirium, no pain, a diagnosis of hysterio-epilepsy was made, and concurred in by the society.

J. H. Blackburn reported a case of hookworm in a family two miles from Bowling Green. Father, mother and six children were heavily infected.

W. C. Strother reported a case of congenital syphilis in a child three weeks old. Irregular enlargements on the right thigh.

T. W. Stone reported a case of acute rheumatism treated with phylacogen, with excellent results.

F. D. Cartwright reported a case of gonorrheal rheumatism.

The program for the next meeting was arranged. Syphilis was decided upon as the subject for discussion.

F. D. Cartwright will conduct a quiz on the subject. L. H. SOUTH, Secretary.

"Case Histories in Neurology," by Dr. E. W. Taylor. Published by W. M. Leonard, Boston. Price \$3.00.

The object of this book, the third volume of the "Case History Series," is to set forth in practical form the fundamental facts regarding the symptomatology, diagnosis, treatment and pathological findings in the more frequent disorders of the nervous system.

The first section presents a General Statement of Diagnostic Methods.

The follow the main divisions of the book: First, Diseases involving Peripheral Nerves; second, Diseases of the Spinal Cord; third, Diseases of the Brain; fourth, Conditions of Undetermined Pathological Basis; fifthly, Psychoneuroses.

The book contains 114 case histories, classified in the sections named.

In addition to the general introduction each chapter has its introduction and summary.

Each case is carefully considered, much attention given to differential diagnosis, and possible methods of treatment are stated.

Numerous graphic illustrations and frequent "notes" commenting upon, and comparing cases, denotes the painstaking teacher of post-graduate classes.

The book is a broad and carefully prepared clinical course in Neurology, dealing with actual cases and supplementing in a way that makes the book not only one of great value, but also very interesting, the teachings of the general systematic text-book.

CARCINOMA OF THE UTERUS.

By HARRY J. PHILLIPS, Louisville.

Carcinoma may arise from any part of the uterine mucosa—from the cylindrical epithelium of the corporal or cervical glands, from the surface cylindrical epithelium of the interior of the uterus, or from the pavement epithelium outside the external os. The variety of the cancer corresponds to the type of epithelium from which it springs. Cylindrical cell carcinoma occurs in the intracervical mucosa, and the pavement cell variety occurs on the external vaginal surface of the cervix. However, this rule is not invariable, because we frequently find cylindrical cell carcinoma outside of the external os, due to eversion of the intracervical mucosa. Again, pavement epithelium may be present in the cervical canal, or even in the cavity of the uterus, and there give rise to pavement cell carcinoma.

Pathologically, we find two varieties of carcinoma. One type is that in which the squamous cells of the cervix have multiplied in an atypical manner and have invaded the deeper tissues; this is the so-called epithelioma, like that which occurs at the junction of the skin and mucosa of the lip. The other type is that in which the cylindrical cells of the interior of the cervix and body of the uterus multiply in an atypical manner, forming the carcinomatous type.

Cancer of the uterus usually begins near the external os, where the cylindrical and pavement epithelium meet. Early in the disease the growth either confines itself chiefly to the

superficial areas, or extends to the submucous structures. When it invades the deeper tissues the diseased part is enlarged, marble-like, hard and friable. The growth rapidly extends and ulcerates early. The margin of the ulcer is irregular, hard and raised. The base is irregular and bleeds easily. The ulcerative process may slowly or rapidly destroy the cervix. This form is called the infiltrating, or nodular carcinoma.

The papillary, or cauliflower cancer, confines itself, in the early stages, to the superficial structures; it begins on the vaginal portion of the cervix, rapidly spreads to the vaginal walls, fills the upper part of the vagina, ulcerates early and bleeds freely. The growth is soft, vascular, and tends to rapid destruction of the cervix and vaginal walls. Rarely the ulcerative process destroys and excavates the walls of the cervix before the disease makes its appearance on the vaginal portion.

ETIOLOGY.

The lower classes of all races are more susceptible to this disease than the higher, and it is more frequent among the white races than among the negroes and the Asiatics. Carcinoma is found very frequently in the cervix, doubtless because the cervix is more exposed to the influence of coitus and to the trauma of parturition. The nulliparous uterus, and more especially the nulliparous cervix, are practically immune. Laceration of the cervix is a clearly recognized predisposing cause; in fact, the disease seldom occurs on the non-lacerated cervix. It is rare before the age of 20 and after 70, not uncommon between 30 and 40; and most common between 40 and 60. The influence of heredity as a cause is considerable.

FREQUENCY.

According to the Registrar-General of Great Britain, in 1900, in England and Wales, 9.97 women per 1,000 of inhabitants, died from cancer, and of all female deaths cancer of the uterus caused 1.3 per cent. In 1890, but 0.83 women per 1,000 of inhabitants died from cancer. In New York, in 1890, the deaths from cancer in women were 0.37 per 1,000, and in 1900 they were 0.43. These figures show the ratio of increase of cancer in women, most of the increase being in cancer of the uterus. And of all cases of cancer which occur in the body, Wm. H. Welch found that the uterus was involved in 29.5 per cent. There is no means of accurately determining the ratio between true cancer, sarcoma and deciduoma malignum. Sarcoma and deciduoma malignum are very rare. The one fact which is impressively evident is the steady increase in cancer of the uterus.

AGE.

In New York, in 1890, 57 per cent of all deaths from cancer were below 45 years of age. The statement that the disease occurs more frequently than formerly in young women is not correct. The apparent greater frequency is due to the fact that a diagnosis of the disease is now made earlier than it formerly was. The maximum number of cases occur above 45 years of age. It is exceedingly rare before 25 years.

SYMPTOMS.

Early in the disease, no special symptoms may manifest themselves. As the disease progresses the following symptoms always appear, viz: hemorrhage, uterine discharges, pain, visceral disorders, and cachexia. As a rule hemorrhage is the first symptom, and is due to the opening of blood vessels by ulceration. This bleeding is too often attributed to irregularities of the menopause, or to a return of the menstrual function after its establishment; and, consequently, the bleeding of carcinoma is often disregarded until the disease has advanced beyond the hope of cure. The appearance of hemorrhage one or more years after the menopause is strong presumptive evidence of cancer, and should cause the physician to make an immediate examination. Likewise, too frequent appearance of the menstrual flow should arouse suspicion and call for careful investigation. The loss of blood is at first slight, and is usually noticed after exercise, straining at stool, or coitus. As the disease advances the hemorrhage increases. It may be intermittent or quite constant, and is usually worst during the menses. The patient's strength is slowly exhausted by a persistent, slow seeping away of the blood; or, on the other hand, severe or even fatal hemor-

rhage may take place. Uterine discharges usually follow soon after the first appearance of hemorrhage. The discharges are watery, foul and very offensive. Early in the disease the discharge may be thin, watery and inodorous. As the ulcerative process increases, it becomes profuse, bloody, purulent, and of a nauseating odor. The bad odor continues to the end and is characteristic of malignant disease. This discharge is called "cancer juice."

In the early stage, while the ulceration is confined to the lower end of the cervix, pain is not constant and, indeed, may be absent. With involvement of the corpus uteri and adjacent structures there may be sharp, cutting pains which are often looked upon as pathognomonic, but which are by no means constant or confined to cancer. The pains are due to pressure on the pelvic nerves, or to involvement of the nerves in the carcinomatous mass; they are usually referred to the pelvis, perineum, or thighs, and usually indicate that the disease is past operative cure. At this stage the limbs become oedematous from pressure and from thrombosis of the pelvic veins. Emboli may be dislodged from the thrombi and carried to the lungs. Then the fatal end is from embolism, septic pneumonia, and pulmonary oedem. Visceral disorders are the result of pressure or involvement of neighboring organs. The bladder becomes irritable. Vesical catarrh, painful micturition, pyuria and cystitis may follow. Nephritis, uremia, hydronephrosis, and atrophy of the kidney are some of the resultant complications. Constipation is common and is usually caused by retention of feces by the patient, who, through fear of pain, voluntarily retains the feces, or the bowel may be so weakened by disease as to be unable to readily empty itself. Diarrhoea is the result of irritation of the bowel by the ulcerative process. There sometimes exists alternating constipation and diarrhoea.

Cachexia is a characteristic symptom and is marked by emaciation, anaemia, a yellowish color of the skin, and great depression of the mind and body. It is caused by supraemia due to the absorption of necrotic tissue, and by malnutrition from loss of appetite, vomiting, pain and hemorrhage.

DIAGNOSIS.

The sooner a cancerous uterus is removed, the greater the security against a recurrence; therefore, the earliest possible diagnosis is imperative. The diagnosis is made by the clinical history, the physical signs, and by microscopic examination.

The clinical history, as just described in this paper, gives strong evidence of cancer but not proof. The physical signs are revealed by examination and inspection. The infiltrating carcinoma of the cervix is recognized as

a hard, thick, nodular, friable growth. The friability is pathognomonic. The ulcers have an irregular, hard, raised margin, and uneven base, and bleed freely. Through the speculum the surface, before ulceration, appears smooth, or nodular, marble-like and glistening. After ulceration, the surface is ragged and irregular, and may show large excavations from the sloughing of the cancerous tissue. The papillomatous, superficial variety appears as a soft, friable, bleeding, cauliflower mass.

Carcinoma of the cervix in the beginning may be overlooked. The cervical wall about the external os may be only slightly thickened, and the induration may appear insignificant. Its extreme friability and persistent bleeding upon slight abrasion will, however, be strong diagnostic factors. Subjective symptoms may even be absent. Microscopic examination is now imperative. Cervical scrapings are usually unfit for examination. A small piece of the unhealthy cervical tissue should be excised and the wound closed by one or two sutures.

Carcinoma of the body of the uterus is likewise, in the beginning, often impossible to recognize. It comes between the ages of 40 and 50. The menstruation is increased and irregular, and this irregularity is often wrongly attributed to the menopause. A slight, watery discharge, even without odor, is strongly diagnostic. If the discharge is malodorous the evidence is much stronger. The general strength and appearance of the patient may be almost up to the standard. Conjoined examination may show nothing except, perhaps, a slight enlargement of the uterus. Life may now depend upon a speedy diagnosis. Everything depends upon curettage and the microscopic findings. Should no microscopic evidence of cancer be found, the curettage must be repeated when hemorrhage returns. In cancer the discharge always recurs promptly. The scrapings are usually more abundant than in benign growths.

Advanced carcinoma of the body of the uterus is, as a rule, easily recognized. The uterus is enlarged, often two or three times its normal size. It is hard, nodular, and more or less fixed. Early fixation also occurs in cancer of the cervix. Positive diagnosis may depend upon the microscope.

The diagnosis of uterine cancer by means of the microscopic examination of curettings from the cervical canal and cavity of the uterus, or the examination of small pieces excised from the vaginal portion, is now generally recognized as one of the most important means of clinical diagnosis. The gross appearance of the curettings is often suggestive, as, instead of the normal, thin, smooth, translucent strips of mucosa, they consist of irregular, shaggy, friable, often granular or waxy-look-

ing strips, which may be of large size. The amount, unless very excessive, is not of great significance, as in simple hyperplastic conditions, retained secundines, etc., a large amount of tissue may be removed. It is often impossible from either the macroscopic or microscopic examination of scrapings, to determine the invasiveness of the tumor, but in the majority of cases the diagnosis offers no special difficulties to the skilled pathologist, as the characteristic alveolar growth, associated with the evidence of rapid cell division and the atypical character of the cells usually found, make up a characteristic picture.

In preparing the curettings for examination, the examination is greatly facilitated if the specimen is carefully prepared, because, if the fragments become shrunken and the cells distorted, a diagnosis is often impossible. A simple and satisfactory method of preparation is as follows:

Immerse the specimen in formalin, 10 per cent. solution, 12 to 24 hours; in alcohol, 95 per cent. solution 12 hours; in absolute alcohol, 12 hours; in alcohol and ether, 12 hours; in celloidin, 12 hours. Block and cut, and stain with haematoxylin and eosin. The curettings should be dropped immediately into the bottle of formalin solution, without previous washing. If a speedier method is desired, the time for leaving in the various solutions may be shortened. If it is desirable to make an immediate diagnosis so as to avoid a second anesthetization, frozen sections may be prepared in the following manner:

The tissue is frozen with ether or carbon-dioxide, sections made and dropped immediately into 10 per cent formalin solution, transferred to 80 per cent. alcohol, washed and stained with haematoxylin and eosin. With this method a diagnosis can be made in from ten to fifteen minutes, about the time necessary to prepare the patient for abdominal section in case a radical operation should be necessary.

It is evident that the physician must be especially upon the alert to detect, first, the slightest symptom pointing to cancer, and then to make at once a rigid bimanual and specular examination of the cervix; or, if the cervix is healthy and cancer of the fundus is suspected, to resort to a diagnostic curettage. The early diagnosis of cancer of the cervix will largely be determined by touch and visual examination. Any irregularity of the cervix which bleeds upon the ordinary vaginal touch should be considered cancer until it is proved otherwise by microscopic examination. Frequently, in my limited experience, I have seen erosions or glandular hypertrophies in cases of laceration of the cervix, which have bled upon touch, and yet there was no breaking off of small particles.

In cases of this character we may proceed upon the assumption that it is merely a lacerated cervix, with a strong suspicion that it may be an early cancer. While we proceed upon the first assumption and either repair or amputate the cervix, we should invariably exclude cancer by a microscopic examination of the excised tissue. In all cases of doubt a pathological diagnosis must be obtained from a skilled specialist. In all cases it must be said that, between a mediocre pathologist and an average clinical diagnostician, the patient stands a very much better chance of cure if the latter's opinion is followed than the former. It is because of the attempt on the part of men not skilled in the determination of pathological changes in the endometrium, or cervical epithelium, to guide the surgeon, that the value of microscopic diagnosis has at times fallen into disrepute. But, if we follow the judgment of a skilled pathologist, very few errors—indeed, much fewer—will be made in clinically doubtful cases than if the clinical side of the question alone is followed. Of course, I am now referring to the doubtful cases, and not to the cases one usually sees. In every city there are pathologists who are reliable, and they should be consulted in all cases of a doubtful character. If this is done, many women will be saved from hysterectomy in which there is no cancer, and others will be hurried at once to a successful operation, who otherwise would have been permitted to go until too late for a cure. Nothing is more reprehensible than to cast aside specimens from a curetage, or from cervical excision, when there is the remotest doubt as to the diagnosis. When submitting tissues to a pathologist for diagnosis, the lines of excision should pass entirely through the suspected area. Every doctor should carry a small, 4 oz., wide-mouthed bottle, containing 4 per cent. formalin, into which scrapings and bits of tissue should at once be dropped.

After the diagnosis of cancer has been made, the next point to be determined is the extent of local involvement, for upon this point depends the decision as to the character of operation to be employed. The vaginal fornix may be the seat of a well-defined ulcerative or cauliflower growth, easily detected by digital examination. But, on the other hand, there may be slight subepithelial metastases outside the area of ulceration, detected as slightly raised or indurated plaques. They are most dangerous because they are most likely to be overlooked. If the cervix is only partly destroyed, and these indurated plaques are distributed over the vaginal fornix, the chief treatment should be the cauterization. If the cervix has been completely destroyed and the vaginal fornix, especially the anterior part near the bladder, is involved, only a palliative

operation is advisable, for no radical operation can offer any hope of cure. Kündrat has demonstrated that the broad ligaments may be the seat of inflammatory exudate rather than of a carcinomatous deposit, and induration, therefore, is not to be taken as an infallible sign of parametrial involvement. If in conjunction with cancer of the cervix there is dense infiltration of one or both broad ligaments, the case is inoperable from the radical standpoint. In judging the extent of a parametrial growth, the pliability of the tissues out near the pelvic wall must be the index, for upon this decision will largely depend the character of surgical intervention. If a wedge-like growth has extended from the cervix out into one or both broad ligaments, and if the outer half or two-thirds are pliable, the radical operation should be performed. On the other hand, if the base of the ligament is stiff and indurated out to the pelvic wall, no operation, or, at most, only a palliative one, may be performed.

DIFFERENTIAL DIAGNOSIS.

Carcinoma must be differentiated from the following diseases: Myoma, benign adenoma, incomplete abortion, endometritis, sarcoma, syphilis, chronic metritis, laceration of the cervix, ichthyosis uteri, and tuberculosis uteri.

Sloughing adenoma, benign adenoma, incomplete abortion and endometritis, each has its peculiar group of symptoms in typical cases. In atypical cases the diagnosis must be confirmed by the microscope. The appearance of early carcinoma of the cervix may be almost identical with that of small cervical myomata or hypertrophy. The diagnostic points are as follows: Myoma and hypertrophy, on section, are hard and resisting. They may undergo erosion, but are not subject to ulceration. On the other hand, carcinoma is friable, narrow-like, and always ulcerative.

Sarcoma has much the same clinical history as cancer, and is recognized only by the microscope.

Syphilis will be known by the clinical history. Specific treatment should clear up doubtful cases.

Laceration of the cervix presents inflammatory and mechanical results that may closely resemble carcinoma of the cervix.

In the vast majority of cases death is from marasmus or anæmia, or both. Hemorrhage, although it may slowly exhaust the patient, is rarely a direct cause of death. Fatal peritonitis from extension of the disease is unusual.

PROGNOSIS.

The sole hope of radical cure lies in surgical removal of the carcinoma. All drugs are of questionable value or useless. If the dis-

case has advanced beyond the limits of a radical operation, death in the near future is inevitable. The disease will sometimes destroy life in a few months or weeks; or, it may for a time become apparently inactive, or develop very slowly and then go on to a rapid termination. The prognosis as to the limit of life should always be guarded. A general statement that death is likely to occur within one year will usually be safe.

TREATMENT.

The treatment is radical when the disease has not extended beyond the limits of entire removal; palliative when it cannot all be removed. The radical treatment should always be complete hysterectomy. The old practice of high amputation of the cervix for cervical cancer should never be resorted to, for one can never be certain that the disease is not also present and unrecognized in the corpus uteri. Hysterectomy is indicated if the disease is limited to the uterus. Such limitation will be inferred, (1) by the normal mobility of the uterus; (2) by the absence of any enlargement of the lymphatic glands in the parametria; (3) by the absence of the disease on the vaginal walls. Enlargement of the glands indicates that the disease has extended beyond the uterus. This does not positively contraindicate hysterectomy, but renders the prognosis less favorable. Whether enlarged or not, the glands should, if possible, be removed. The relation of these glands to the carcinomatous uterus offers a close analogy to the relations of the axillary and subclavian glands to cancer of the breast. Extension of cancer to the vaginal walls, if slight, does not contraindicate hysterectomy, provided the diseased portion of the vagina can be removed with the uterus. Extensive involvement of the vagina and fixation of the uterus in surrounding cancer contraindicate the operation. When the disease has passed beyond the hope of radical cure, but not beyond the limits of palliative hysterectomy, hysterectomy is sometimes performed for temporary relief.

The operative technique of hysterectomy is outside the scope of this paper. The writer, however, wishes to give some good and valid reasons why abdominal hysterectomy should always be performed, when operative measures offer any hope of cure whatsoever. Inasmuch as the abdominal operation allows the operator to secure the ovarian vessels at the pelvic brim, and the uterine arteries outside the ureters; and, again, as by this operation not only the individual lymph glands, but also the lymph channels in the broad ligaments and the greater part of the vagina, if this should be necessary, can be removed, I always prefer this operation for cancer of the cervix or the corpus, if a radical operation is

indicated. The operation permits the broadest section of tissue in an uninvolved field, with accurate removal of lymphatics, thus complying with the first surgical requisite. It further permits of this being done under a preliminary haemostasis, and the vessels and lymphatics are severed before the uterus is subjected to any squeezing, thus eliminating the possibility of extrusion of the cancer elements into the absorbents. Besides, complications can be better dealt with by this route. The abdominal route permits the surgeon to remove all those structures to which cancer normally extends, and in which it has a tendency to recur. In some quarters there is a tendency to apply the vaginal operation to the early cases, reserving for the abdominal operation those in which there are complications, or in which extension of the cancer outside the cervix has taken place. If cancer were free from the tendency to recur, such selection might be proper, but by adopting such tactics the operator is neither just to the operation nor to his patient. If the abdominal operation is the preferable procedure for accomplishing all that can be accomplished for this disease, when complications already exist, it is, I believe, still more strongly indicated in the early cases. No one has a right to rob a patient suffering from cancer of even a fraction of a per cent. of immunity from recurrence. In all cases it is the surgeon's duty to do the most radical operation possible, provided this complies with the surgical and anatomical requirements of the case and does not carry a prohibitive mortality. A woman with early cancer has a greater right to a radical operation than one with the disease in a late stage, for her chances of recovery and of acquiring immunity against recurrence are greater.

The medical treatment of cancer of the uterus consists in the removal of all sloughy and necrotic tissues, so far as is possible, in order to secure cleanliness. After the removal of all the diseased tissues possible by the curette or cautery, further removal of tissue can be secured by the following method: Thin, circular pieces of cotton, about one-half an inch in diameter, are squeezed out in an aqueous solution of chloride of zinc, of 20 per cent. strength. These are packed singly around the cervical cavity so as to completely fill it and come in contact with all diseased surface. Over the whole the vagina is packed with large pieces of cotton wrung out in a saturated solution of bicarbonate of soda. This is important, because, as the serum seeps through the zinc-soaked cotton, it would cauterize the vagina unless neutralized by the soda solution. This dressing is left in position for two or three days. Upon its removal the cervical cavity will be found lined with a gray-

ish slough. Two days later this can be picked away by forceps. In this way repeated sloughs can be produced and removed. When a physician is not provided with an actual canter, this treatment by means of caustic solutions can be begun after the operation for removal of the cancerous mass, as soon as the bleeding ceases. I have tried a number of methods of local treatment and find this the simplest and best. After all unhealthy tissue possible has been removed by this method, the patient should be put on 5 grain doses of thyroid extract. I have seen good results follow in many cases, and in every case the disease has been arrested, for a time at least. The thyroid should be pushed to the point of tolerance.

When pain in carcinoma becomes severe enough, it must be relieved by opiates, using codein first, either externally or by suppositories; then stronger preparations of opium. Section of the spinal nerves has never been resorted to in any of my cases.

Hemorrhage is best treated by tamponade of vinegar-soaked cotton. As the pelvis becomes blocked with cancer masses, obstruction of the bowel occurs. It is then the surgeon's duty to perform colostomy.

The rapidity of the growth of cancer of the uterus may be checked by ligating the blood vessels which nourish it. The plan is to ligate, through the median abdominal incision, the ovarian, the internal iliac and the obturator arteries. After the vessels are ligated and the operation completed, the cancer masses are scraped away through the vagina, and the freest drainage provided for the escape of the discharges. The patient is put upon thyroid extract and tonics. By this treatment life is much prolonged and suffering diminished.

OTHER METHODS OF TREATMENT.

Serum therapy has been employed in a number of cases and in various forms, but without benefit. The cases reported to be relieved have, upon examination, proved worthless for statistics.

Owing to the inaccessibility of the cancerous uterus, the X-ray treatment can be carried out only with difficulty. Injections of various drugs into the cancer mass, such as methylene blue and alcohol, have been employed, but with little or no benefit.

DISCUSSION.

J. Garland Sherrill: This is always a live topic for discussion. I cannot agree with one or two statements made by the essayist, although, in the main, his paper is a very fine one. The question of heredity has, I think at the present time, been pretty much laid aside, as a causative factor in cancer. Upon looking into the question thoroughly, investigators have recently discovered that about as many patients, who give abso-

lutely no hereditary history of cancer, suffer from this disease, as those who give a history of heredity so far as cancer is concerned. Therefore, less attention is attached to the possibility of heredity being a factor in the causation of cancer now than formerly.

It seems to me that the most important thing in the study of cancer of the uterus is to learn how to make the diagnosis early, upon which point great stress is laid by practically all authors. It is a very difficult thing to make an early diagnosis of carcinoma of the uterus. There are several conditions with which it may be confused—a retained secundines, for instance. I saw one case in which bleeding had kept up for six months, without any clear history of a miscarriage. However, the fact that upon touching the external parts there was no hemorrhage, made me suspicious of a miscarriage, and careful questioning elicited the fact that the patient had miscarried about six months prior to the time I saw her. Curettment confirmed this fact, and showed that a large piece of the placenta had been retained. This woman made a perfect recovery and, a couple of years later, was delivered of a fine child.

Again, we may have a case of proliferating endometritis, with free bleeding at and between the periods. I can recall several such cases in my early practice. I particularly recall one case in which I assisted the attendant in doing a curettment half a dozen times, and for a time after each curettment she would be better. Finally, after a number of curettments she made a permanent recovery and is living to-day.

Again, we may have a syphilitic ulcer on the cervix. Syphilis of the cervix, while rather rare, does occur, and when it does occur it is by no means easy to make the diagnosis. I consider it one of the most difficult conditions to differentiate from carcinoma of the uterus within a certain period of time. However, within a few weeks, it will be followed by the usual symptoms. In addition to this, we now have the Wassermann test, which is of great assistance in differentiating between these conditions.

The symptom that we all depend upon is bleeding. First, after the menopause, as mentioned by the essayist. Upon examining the cervix with the aid of a speculum, we find that it bleeds rather easily under the touch. However, we must not overlook the fact that a cervix which has been lacerated looks very red and rosy, and bleeds at times, but still it is not malignant. I would advise every doctor, in cases where he is suspicious of malignancy, to have a curettment made and the scrapings examined under the microscope, which is the only way of positively determining the nature of the trouble. We should also remember however, that curettment of a cancerous cervix may simply ignite the disease. Therefore, I believe that curettment should be followed promptly by hysterectomy in cases where the

microscope proves it to be a cancerous lesion.

As to the operation itself, I think it should be a radical one. Why is it that these cases do not come to operation early? One reason is that these women do not go to the doctor for hemorrhage. Another reason is that, when the average woman suspects that she has a cancer, she keeps it to herself. Most of the laity seem to believe that when one develops cancer, it necessarily means certain death, when the truth of the matter is that, when operated upon early, the mortality is low, and permanent cures are effected in about 40 per cent. of cases. Therefore, we should urge women who suffer from symptoms of this character to come to examination early, and the physician should examine such patients, not once, but many times; telling the patient to come back in the course of a few weeks, until you are sure that no cancer exists.

Now, as to the operation that should be done. It requires a very competent observer to tell when a case is operable and when it is not. This should only be passed upon by a man who is able to tell from experience how far it is safe to go and save the patient's life. Radical operation is undoubtedly best accomplished by the abdominal method. I make it a rule to first thoroughly prepare the vagina, making a dissection of the mucosa for some distance from the cervix; then dissecting around the cervix for 1-2 or 3-4 of an inch, and getting the mucous membrane of the vagina so that it can be sutured over a small piece of gauze, when the cancer is in the early stages. Then I stop the vaginal work, change gloves, and proceed to do an abdominal section, going in through the cavity and doing a Wertheim operation.

This operation consists in tying the vessels clear out to the brim of the pelvis. Some operators put catheters into the ureters before beginning the dissection. I recall one case where, in order to dissect a gland off of the left side, I had to completely expose the ureter for a distance of perhaps four inches. Later the damage to the ureter resulted in the formation of an ureteral fistula, which remained for a month or six weeks. Under cautery in the vagina, and the use of ligature paste, the fistula closed. This was a case which had apparently gone beyond the possibility of a cure, and yet the patient is still living.

What can we do for those patients who come to us after the possibility of a cure by radical operation has passed? A very large percentage of the cases that I have seen have come to the operating table too late for any radical work. What are we going to do for these patients? With a large cauliflower growth on the cervix, little can be accomplished. In cancer of the body, there is much more hope for permanent relief. Cancer of the cervix can be treated even after the time for radical operation has passed, life prolonged for from twelve to eighteen months, and for a time, at least, the patient will be free from discomfort.

As the essayist has stated, the majority of cases die within twelve months after the condition is discovered, but by palliative treatment, properly carried out, much may be done for these patients.

I believe that it is rarely necessary to tie off the blood supply of the uterus before doing an actual cautery operation. With a large, sharp curette the necrotic tissue can be rapidly scraped out. Then, the walls of the vagina being protected well by retractors, and by wet gauze, the cautery is applied very freely to the uterine structures, being careful to avoid damaging the bladder and rectum, or any of the surrounding tissues. This tissue is packed with bicarbonate of sodium to relieve any pain, and later we may use the other remedies mentioned by the essayist—and there are few that are better than eldorado of zinc, applied as the doctor has described. Gellhorn has in recent years advised the use of acetone in these cases. Do not stop with one cauterization, but repeat it two or three times if recurrence takes place. In one or two instances, recovery has taken place under this treatment. It should be repeated again and again, just as long as there is any tissue to work with between the vagina, bladder and rectum.

Bernard J. O'Connor: What is the immediate mortality of the Wertheim operation?

J. Garland Sherrill: I think it is not more than 4 or 5 per cent. In cases properly selected, which are not too far gone, it should not be more than this in the hands of a skilled operator. No man should undertake this operation who has not done a large number of abdominal sections; otherwise, he will be sorry.

I wish to utter a word of caution in regard to any operation for the removal of carcinoma of the uterus; that is, we should be very careful to protect all of the structures with which the uterine body or uterine surface might come in contact. I recall one case in which I was not absolutely certain that the woman had a carcinoma. She had a nodule about the size of a pea on the cervix which bled at a touch, and I remarked that, if this was a case of cancer of the cervix, it certainly was an early diagnosis, and I hoped for a very brilliant result. Using every precaution, I made the vaginal section in the usual way, covering every surface so that it would not come in contact with the growth. Then I cleaned up carefully, opened the abdomen, and removed the cervix, employing, as I thought, every precaution to prevent contact. At the end of six months this woman had a recurrence in the abdominal wall, without any evidence of connection between the wall and the deeper tissues. She also had a recurrence in the broad ligament. Therefore, I believe that transplantation can and does take place, and deem it of the utmost importance to thoroughly protect the vaginal and abdominal wounds in removing the cervix.

C. H. Harris: I have a case of carcinoma of the cervix under observation at the present time,

which is inoperable. The mass has pushed the bladder up and the rectum down. The use of acetone was begun about a year ago. The other day we put in a speculum and simply saturated everything with acetone. It controls the hemorrhage and seems to render the patient more comfortable for a while. I cannot keep up the applications every other day on account of the pain it causes. At the present time I am using acetone once a week, and I believe it is one of the best palliative measures that we have in cancer of the cervix.

Bernard J. O'Connor: I wish to emphasize what the essayist and Dr. Sherrill have said in regard to early diagnosis, which is a most important point in connection with cancer of the uterus. It has been shown that the old idea, that cachexia, loss of weight, and pain are symptoms of cancer, is a fallacy; that these are symptoms of approaching death rather than of the tumor itself. We must be guided by hemorrhage, and the results of repeated examinations.

The points that have been brought out in connection with the pathology of cancer are very important. It is unquestionably a very difficult matter, even for an expert pathologist, to say when cancer is absent. Of course, when we find cancerous tissue, we can say positively that the patient has a cancer, but occasionally even the best of us will not happen to strike a field or section in which the cancerous growth has manifested itself. Therefore, the surgeon should not rely absolutely upon the report of the pathologist for the diagnosis.

In my opinion, no one but a skilled surgeon should attempt the Wertheim operation. If I am not mistaken, the primary mortality from this operation is much higher than the figures given by Dr. Sherrill in his discussion.

Montgomery, who is really the father of the method of treating carcinoma of the cervix with actual cautery, holds that quite a large percentage of cases—possibly as many as 50 per cent.—are cured by this means; or, at least, live from fifteen to eighteen years afterwards. He cauterizes the uterus very thoroughly, and it is really almost equivalent to an hysterectomy.

H. J. Farbach: I think Dr. O'Connor brought out a very important point when he said that we cannot absolutely rely upon laboratory methods for the diagnosis of cancer of the uterus; the tail should not wag the dog.

I was in hope that the essayist and Dr. Sherrill, in his discussion, would say something about the etiology of cancer. That is the paramount question to-day, and I believe that most men are coming to believe more and more in the infectious nature of cancer; that it appears in devitalized tissue of low resistance; that it appears in parts that are exposed to infection.

In regard to the treatment of inoperable cases, the Italian school has, in the past few years, tried out the autolysate treatment, and

one man, in a report of eighteen cases treated by this method, says that ten of them are still living after six years, with no evidence of the disease other than slight induration.

Their theory is based upon the fact that embryonic tissues seem to be immune to carcinomatous attack. A fetus, anywhere from the third to the eighth month, is obtained under sterile conditions, placed in a sterile vessel and covered with paraffine and kept at a temperature of from 98 to 100 degrees F. until complete autolyzed. This material is then injected directly into the cancerous growth (after having removed as much of the cancerous tissue as possible) in quantities of from one to ten c.c. The injection sets up a necrosis, and the necrotic tissue is removed from time to time and the injection repeated.

Harry J. Phillips, (Closing): I wish to thank the gentlemen for their discussion. In selecting this subject I thought it would be of interest to all of us—the internist, the pathologist, the gynecologist and the surgeon, and that it would be liberally discussed and freely criticised.

As to Dr. Sherrill's remarks in regard to differentiating between carcinoma and a syphilitic ulcer of the uterus, I would say that, in cases where we suspect syphilis, the patient should be put upon specific treatment, under which it will promptly clear up if the trouble is syphilitic.

In the case of retained secundine, mentioned by Dr. Sherrill, this might have brought about a condition of deciduoma maligna, or cancer within the uterus, and his patient was fortunate in not having developed such a condition.

Another symptom that I have noticed and have been careful to look for, is a profuse leucorrhoeal discharge in women who have been subject to leucorrhoeal discharge, and any leucorrhoeal discharge in women who have not previously been troubled with such a condition. This will bear close watching, because it is sometimes one of the earliest symptoms of malignant disease of the uterus.

In the past 18 or 19 years I have had some fifteen cases of carcinoma of the uterus of various types. Several of these were operated upon in time. One of them is living and apparently in good health six years after the operation; another, four years after the operation. Two, who were operated upon nearly three years ago have shown no evidence of recurrence.

I do not think we can depend upon digital examination for our diagnosis. The average diagnostician may think that he can put his fingers into a woman's vagina and tell whether or not she has malignant disease, but I do not believe any one can be positive about it without a specular examination. We can see things that we cannot feel, and I make a practice of using a speculum in addition to my fingers.

At the present time I have under observation three women, all of whom are subject to considerable bleeding at the menstrual period, and some

oozing between the periods. The great trouble is to convince these patients that they have malignant disease. As Dr. Sherrill has said, they do not like to entertain the idea that they have what they consider an incurable disease, and the result is that the majority of them do not come to the doctor until the disease has begun to undermine their constitution, and oftentimes when they do come, they have passed the stage when operative procedure will do any good.

INDICATIONS FOR OPERATIONS ON THE BLOOD VESSELS.

By JOHN W. PRICE, Jr., Louisville.

The first operations which were performed on the blood vessels were, venesection and suture of the arteries. The latter was successfully performed in 1759.

Anastomosis of a vein to a vein was first attempted on a dog, in 1877, by Eck. It was a successful anastomosis between the vena cava and portal vein.

In 1892 Vignolo successfully performed an end to end anastomosis of artery and vein.

In 1898 Glauek was successful in transplanting a piece of the carotid between the two cut ends of the jugular vein. These are the only two successful cases of anastomosis of the blood vessel which I have been able to find before the development of the wonderful technique of Carrel which was reported about 1902. Carrel's first reported attempt to do an arteriovenous anastomosis resulted in death of the dog, two days after the operation from hemorrhage.

San Martín y Satrustegui, in 1902, attempted a jugular-carotid anastomosis on three goats, without success.

In 1905 Garrel and Guthrie reported a series of 13 arteriovenous anastomoses in animals with only a single failure.

Carrel in a very recent article on the technique of vascular anastomosis describes his methods in detail as he applies them to-day. He describes arterial anastomosis (a) end-to-end (b) termino-lateral; venous anastomosis; and arteriovenous anastomosis (a) end-to-end (b) termino-lateral.

I have applied the Carrel technique on dogs and have found it very difficult to manage the stay-sutures and make a good union, and so I have had made this little device which you may see to-night.

In order to determine the indications for operations on the blood vessels it seems that we may find it helpful to consider the cases in which these operations have been performed and note the results and then draw our conclusions. It may be possible then to discover other conditions which may be benefited by vascular operations.

First, vascular operation—venesection. Ortuier has found venesection to give relief in the following conditions:

Broken compensation, especially when there is threatened pulmonary edema, venous cerebral hyperemia and threatened heart-paralysis. The reduction of the blood mass and the stimulation of the circulation often make the dilated heart once more perform its function. In case of threatened heart paralysis venesection may be effective when stimulants prove powerless and death is imminent, the patient being decidedly cyanotic with blue and cold extremities and a thread-like pulse.

Second indication for venesection is in cases of threatened cerebral hemorrhage and even when the cerebral hemorrhage is actually present, as the result of arteriosclerosis or nephritis.

The third is in plethora, especially when symptoms of active hyperemia and congestion are conspicuous (face, cheek and ears intensely red, almost purple, and the calibre of the peripheral vessels, especially of the face, enlarged).

In croupous pneumonia it is indicated when the patient is strong with a full and almost bounding pulse, deep red or slightly cyanotic face, dyspnoea and pain, and abundant bloody sputum. And when there is a marked accentuation of the second pulmonary tone, and often a relatively acute dilatation of the heart.

Another indication for venesection is pulmonary edema, either acute inflammatory edema, or edema in nephritis or in heart lesions.

Kidney disease is the next indication. It is useful in cases of acute uremia in chronic Bright's disease with good heart action or cerebral hemorrhage, either threatened or actually present, and where severe renal symptoms are present in all kinds of severe infection, such as typhoid and pneumonia. Sænzé warmly advocated phlebotomy in acute nephritis with acute uræmic symptoms, particularly convulsions. Dieulafoy advises it in relatively slight uræmia because it lessens the chances of the acute nephritis becoming chronic.

Chlorosis is another indication for venesection according to Dyes, Wilhelm, Scherbert. Virordt discovered that slight losses of blood increase the number of red corpuscles; Lesser discovered that they increase the hæmoglobin contents. Neusser, Schipero-weitsch assumed that the loss of blood stimulates the formation of new blood.

Venesection is also indicated in poisoning by illuminating gas and carbon monoxid; the loss of blood is to be followed by immediate infusion of salt solution or transfusion.

Venesection is also indicated in sun stroke and gives good result.

Second. Vascular operation transfusion.

The second vascular operation of importance is the direct transfusion of blood from one patient to another. The greatest stimulus to this work has been due to the efforts of Crile. The methods of doing this operation have been the end-to-end suture described by Carrel and approximation by apparatus devised by Crile, Elsberg, Soresi and Levin, and vessel inter-locking by end or lateral implantation by Hartwell, and an inter-position of a foreign body-link by Brewer and Frank. Bernheim has made a modification of Crile's cannula which is easy of application but we prefer end-to-end suture.

In 1907 Crile reported his method of doing the transfusion and stated that he had used it in 32 clinical cases but did not state what the cases were.

In 1908 Ottenberg reported two cases of transfusion for secondary anemia. The immediate results were satisfactory but both cases terminated fatally from a continuation of the original diseases.

In 1908 F. O. Allen performed transfusion in a case of leucophilia. The patient was a boy 12 years old who had bled four days previous to admission to the Hospital. He was comatose, very pale, skin flabby and waxy, and there was a thin stream of blood oozing from the mouth. The oozing continued for two days and then transfusion was done. During the operation the mental condition became bright enough for him to complain of pain and to call the doctor bad names. Allen states the amount of blood passed was not definitely known on account of difficulty in making anastomosis, but two days later the haemoglobin had risen from 5 to 14 per cent and one month later the haemoglobin was 68 per cent and the red blood cells 3,938,000. The relief was temporary, as the boy was admitted to the hospital six months later with a haemoglobin percentage of 15 per cent.

In 1909 Wm. A. Downes reports doing a transfusion for the purpose of removing a patient from a category of a doubtful surgical risk to that of one of reasonable certainty.

The patient was a child two years and two months old. He presented a lump in the left side of the abdomen. Blood examination showed haemoglobin 45 per cent.; red blood corpuscles, 4,960,000; white blood corpuscles, 12,000. Transfusion was continued for 40 minutes and the haemoglobin arose to 80 per cent. The next day it had fallen to 65 or 70 per cent. A nephrectomy was then done and there was no shock after the operation. The patient made a complete recovery.

Direct transfusion has been used in the fol-

lowing ten cases reported by Pool and McClure:

First. Illuminating gas poisoning. Result marked improvement—patient lived for a week and died of hypostatic pneumonia. They say, "In regard to the treatment of illuminating gas poisoning by infusion the case shows that at least astonishing temporary effects may follow transfusion. The patient was resuscitated from a moribund condition, the respiration and heart action quickly became normal and remained so for several days. The red cells from the donor must become carriers of oxygen. In this respect the clinical findings were similar to those obtained by Crile in experiments on dogs. If the degree of poisoning is such as to cause cerebral softening, permanent benefit cannot be expected."

Second. Secondary anemia; haemophilia. Result—discharged cured 24 days after the transfusion. Three months later patient's condition and color were excellent.

Third. Secondary anemia carcinoma of the stomach. Blood examined before transfusion showed haemoglobin 31 per cent.; red blood cells 2,210,000. After transfusion haemoglobin 44 per cent.; red blood cells 4,600,000; patient was discharged six days later much improved. Seven months later patient died at home. No autopsy.

Fourth. Secondary anemia, biliary fistula, multiple hemorrhages and senility. Patient 80 years old. Before transfusion blood examination showed haemoglobin 18 per cent.; red blood cells 1,856,000; after transfusion haemoglobin was 40 per cent.; red blood cells 2,380,000. Two days after transfusion patient had a profuse rectal hemorrhage and died soon afterwards. No autopsy.

Fifth. Septic endocarditis; septicemia.

Ten minutes after the beginning of the transfusion the patient became restless and irrational, cyanosed, pulse rapid and irregular, and respiration rapid and almost stertorous. It seemed extremely dangerous to continue so the transfusion was immediately stopped. Patient died on the 19th day after the transfusion and after an illness of almost eight months. No autopsy.

Sixth. Secondary anemia following puerperal septicemia.

The blood examination showed haemoglobin 34 per cent.; red blood cells 1,284,000; white blood cells 8,500. The patient's general condition was so poor that a transfusion was done in the hope of making her better able to stand an operation. The patient was transfused and the blood examination showed haemoglobin 54 per cent.; red blood cells 3,608,000; patient continued to improve for six days, haemoglobin becoming as high as 62 per cent, and the red blood cells 4,600,000; during the

next three weeks there was a steady fall in the haemoglobin per cent. and also the number of red cells but no operation was performed and patient improved. At the time of her discharge, about two months later, her condition was so good that she was able to return at once to her household duties.

Seventh. This patient, 43 years old, was suffering with profound anemia. On admission she was almost moribund. Blood examination showed 600,000 blood cells and 16 per cent. haemoglobin. Transfusion was immediately done with slight improvement. The next day a second transfusion was made with marked improvement. The third transfusion was ten days later because the patient's blood and general condition had begun to show a marked change for the worse. The result was, considerable and prolonged improvement. The patient was discharged from the hospital five months later and blood examination showed haemoglobin 70 per cent.; red blood cells 3,150,000. The cause of the anemia in this case was not definitely determined. It is interesting to note that after the third transfusion the patient developed pneumonia in the right lower base and later pleurisy with effusion on the left side. The effusion was tapped ten times, and as much as 20 to 30 ounces of blood-tinged fluid was removed at one tapping.

Eighth. Papilloma of the bladder, excision followed by secondary anemia. Five and one-half hours after the operation the patient was comatose and practically moribund. Haemoglobin 34 per cent.; red blood cells 1,500,000; pulse 156 per minute. Transfusion was performed and the blood was allowed to flow 40 minutes. The author reports that the patient's general condition underwent a marked improvement during the transfusion. The transfusion would have been continued but the donor began to show the effect of the loss of blood. Examination of the blood two hours after the transfusion showed haemoglobin 46 per cent.; pulse 140. The patient continued to steadily improve and was discharged in about six weeks. Examination of blood showed red blood cells 4,112,000; haemoglobin 75 per cent.

Ninth. Infected fibroid of the uterus; suppurative metritis; multiple metastatic abscess of thigh; pyaemia. On admission of patient temperature was 102 degrees; pulse 124; respirations 28. Haemoglobin 30 per cent.; leucocytosis 40,000. General condition was so poor that it was thought she could not stand an operation. She was transfused eight days after admission and the haemoglobin arose gradually from 18 per cent. to 40 per cent. The afternoon after the transfusion a dull urethral discharge was done and some tissue and considerable pus were brought away. For a few

days the patient's condition was excellent but during the following six days the haemoglobin dropped to 18 per cent. From this time on, however, the patient began to gradually gain ground and was discharged in about three months. A month later she was seen and was apparently in perfect health. She had gained weight even to excess and her color was that of a robust and healthy woman.

Tenth. Secondary anemia following hemorrhage from a circooid aneurysm of the face. Before the transfusion haemoglobin fluctuated between 19 and 40 per cent. In this case the transfusion was not successful because the donor was highly neurotic.

Hemophilia. This case is reported by Dr. Chas. Goodman. Patient, boy two and one-half years of age. On admission it was found that the patient had several wounds about the mouth and face which had been sustained in a fall from a fire-escape. All of the wounds were oozing. The previous history was that the child had shown a tendency to develop black and blue spots on the body upon the slightest injury and that they would last from six to eight weeks. Ritual circumcision performed on the 8th day after birth was followed by continued bleeding for several days. When a year and a half old the child cut its finger and the wound bled for two weeks. Eight months before admission the child fell and cut its gums and this wound continued to ooze for several months. Blood examination on admission showed haemoglobin 12 per cent.; and red blood cells less than a million. Transfusion was immediately done and after ten minutes there was a slight change in the color of the lips; there was only an occasional flutter of the child's pulse. The transfusion was continued 28 minutes. At the end of that time the pulse was regular, of good quality, and 140 in frequency. The ears, cheeks and lips, previously waxy, had now become pink. The haemoglobin showed 70 per cent. An hour and a half after the transfusion there was a sudden rise in the temperature to 106.4 degrees and pulse 190. This gradually subsided without treatment and 12 hours later temperature was 99 degrees and pulse 140. The child made an uninterrupted recovery and was discharged from the hospital at the end of eighteen days, blood examination showing haemoglobin 60 per cent.; red blood cells 3,400,000. After spending three weeks at the seashore, examination showed 5,000,000 blood cells and 80 per cent. haemoglobin. Recently the child suffered from an infected scalp wound with cellulitis which required extensive incisions. The wound healed gradually without any tendency to hemorrhage.

Third vascular operation. Grafting, or

transplantation of a segment of vein or artery between the cut end of two vessels.

In 1905 Carrel advocated the use of venous grafting in the treatment of aneurysms and of certain traumatic lesions of arteries. Carrel had shown by experiments in 1902 and 1903 that arteriovenous anastomosis made with a proper technique would remain normal and that a vein transplanted on an artery reacts against the increase of the pressure by thickening of its wall. He demonstrated that veins could be safely grafted on arteries. He further showed that thrombosis, observed by previous experimenters, was not due to a biological, but merely to a surgical cause, and that, with a proper technique, positive results could be easily obtained.

In 1907 Watts performed, several times, a graft of a segment of a jugular vein on the carotid artery. Stich, Fiches and V. Schmeiden, also obtained positive results experimentally. Goyanes in 1906 performed a transplantation of the popliteal vein on the popliteal artery after the excision of an aneurysm, and his patient recovered.

Lexer in 1907, in a case of axillary aneurysm, performed a graft of a segment of saphenous vein. His patient was in poor general condition and died after a short time.

Bernheim in January, 1910, in the clinic of Dr. W. S. Halsted transplanted five inches of the left saphenous vein between the cut ends of the right popliteal artery and vein. Dr. Halsted had previously removed a sarcoma originating in the popliteal nerve and involving the popliteal artery and vein, so that, after the operation, there was a defect of four inches between the cut ends of the vessel. The leg continued to have a good circulation and the patient was able to walk when he left the hospital. He died eighteen months after the operation.

In a case of threatened gangrene in January, 1911, Bernheim transplanted one inch of the femoral vein between the femoral artery and the femoral vein. The section of vein which was used for transplanting was removed from the proximal end of the vein. This was necessary because he was unable to do an end-to-end anastomosis between the artery and vein because he had made the mistake of cutting the vein and artery at the same level and had not allowed for the usual retraction following the section of any vessel.

Fourth vascular operation. Arterial end-to-end anastomosis. Experimentally the first successful end-to-end anastomosis was made in 1894 by Robert Abbe, of New York. He tied each end of the divided abdominal aorta of a cat with a fine silk thread. Quierole and Msini in 1905 introduced an appliance consisting of a tube of glass through which one end of the artery was threaded and enuff

ed back and then invaginated into the other end and held in place by a ligature. Nitze in 1897 demonstrated a similar aid made of ivory. Payr in 1900 described two appliances made of an absorbable material—magnesium. For a short time these were quite popular and from one form of these the Crile cannula has been developed. Murphy, of Chicago, in 1897 described a successful method of anastomosis by invagination. Jabonlay and Brian and Slomoni, independent of each other, devised a similar technique. The method of Jabonlay and Brian was improved by their former pupil Carrel into the method which is now most generally used.

The advantage of being trained to apply this technique was successfully demonstrated by Ehrenfried and Boothby in the following case: The patient had been stabbed in the groin and it was found upon examination that the femoral artery had been completely severed. An end-to-end anastomosis was immediately performed by the Carrel method. The recovery was rapid and uneventful despite the weakness of the patient from loss of blood. The patient was discharged at the end of two weeks.

Fifth vascular operation. Arteriovenous anastomosis. This form of operation was first attempted in 1881 by Francois Franck. It was unsuccessful.

The first clinical case was that of San Martin y Satrustegui who, in 1902, attempted an arteriovenous anastomosis in man as a means of treating gangrene of the extremities. The immediate result was satisfactory but extension of gangrene called for amputation on the sixth day after the anastomosis had been made.

The second case reported by the same author was also unsuccessful and amputation had to be performed. Jabonlay operated on the third case. He made a lateral union of the vessels. The immediate result appeared hopeful but on the 28th day amputation at the thigh was done.

The first successful operation in man was in 1907. Doberauer reports a case of a woman with embolism of the humeral artery with threatened gangrene. The artery was twice opened and the clot removed. A thrombus formed a third time and gangrene progressed. The axillary artery and vein were anastomosed and active pulsations continued for eight days. Nothing is reported after that.

The second successful case was reported by Ballance in 1908. The woman was a patient 75 years old with senile gangrene of the toes of the right foot which was beginning to extend to the dorsum of the foot. Anastomosis was made between the femoral artery and vein, after which the discoloration of two

of the toes disappeared and gangrene made no progress in the following months, and demarcation in the already affected toes occurred. Death occurred from gangrene of the intestines five months after the operation.

The third successful case was reported by Wieting in 1908. The patient was a man 40 years old with threatened gangrene of the left leg due to arteriosclerosis (amputation of the right leg, first below and then above the knee, had been performed on account of the gangrene). A lateral implantation of the femoral artery into the vein was performed at the apex of Scarpa's triangle. After the operation the toes and foot became warm and pink and the pain disappeared. Two months after the operation there was no signs of the gangrene. The operation was a complete success.

Three operations have been performed on account of traumatic gangrene.

Beck reports a case with compound comminuted fracture of the leg below the knee. The anterior tibular artery was exposed and an anastomosis was made between the artery and one of the large veins. The crushed leg acquired a brighter color and more warmth and remained so without further signs of gangrene for 48 hours and then the man died of pneumonia.

Lubert and Fialle report the case in 1909 of a man who had a bullet wound penetrating the femoral artery, the popliteal artery and vein. An end-to-end anastomosis of the popliteal artery and vein was made but was unsuccessful and the thigh had to be amputated. This seems to be one case in which a proper technique would undoubtedly have saved the patient's leg.

Torrance in 1907 reports the case of a man with a fracture of the right leg and rupture of the posterior tibial artery. The anterior tibial artery was transplanted in the saphenous vein. Pulsations continued for a day and then stopped. Four months later the leg was amputated on account of disease of the bone.

Orphan reports a case in 1907 with suppurating gangrene of the small toe. Anastomosis between the popliteal artery and vein was performed which was unsuccessful, the leg had to be amputated.

On account of presenile endarteritis arteriovenous anastomosis has been performed three times. Lillienthal reports a case of a man, age 20, with gangrene of the feet. The operation was unsuccessful. Patient was very much shocked and died 31 hours later without showing any signs of improvement.

Beck in 1910 reports a case of a young colored man with gangrene of both feet extending several inches above the ankle. Cause unknown. An end-to-end anastomosis of the femoral artery and vein was done by Carrel's

method. The patient did not improve and a double amputation was performed through the thighs. The vessels in both legs showed endarteritis.

Von Schmiedon in 1910 attempted an anastomosis for presenile gangrene in a patient 29 years old. The anastomosis could not be done because the artery was found obliterated.

Halstead and Vaughan have recently reported two cases of arteriovenous anastomosis in the treatment of gangrene of the extremities. Both cases were unsuccessful and Halstead and Vaughan close their article with the statement that since the writing of the paper they have had another case of arteriosclerotic gangrene for which they performed amputation rather than anastomosis.

Bertram M. Bernheim in a recent number of the *Annals of Surgery* (February, 1912) reports several cases of arteriovenous anastomosis which were successful. In the case of threatened gangrene, in which he had transplanted a piece of vein between an artery and a vein in one leg with complete success, it was found, about four months later, that the other leg was affected, so a lateral anastomosis was made between the femoral artery and vein. The result was perfectly satisfactory. At the time of his article (eleven months after the first operation and seven months after the second operation) he says the left leg has a circulation apparently as good as normal and gives no pain. The right leg has also apparently normal circulation.

Another case was operated upon for beginning moist gangrene. An end-to-end anastomosis between the femoral artery and vein in Scarpa's triangle was made. Three days later the leg was amputated at the thigh. Anastomosis was found to be working beautifully but was badly selected and the blood vessel operation ought never to have been done because, apparently, the gangrenous process had progressed so far that the nerve had become involved as well as the small vessels; thus making an attempt at saving the limb utterly hopeless.

His next case was for beginning gangrene and an extensive ulcer of the right foot which had been present for two and a half months. An end-to-end anastomosis was made between the femoral artery and vein in Scarpa's triangle and the vessel was found to be two-thirds occluded by an old thrombus. The result of the operation was a complete success.

Another case was one of threatened gangrene with a thrombus in the axillary artery. He went above the site of the thrombus and made an end-to-end anastomosis between the artery and vein at the lower border of the axilla. I consider this operation successful because he states that the patient left the hospital in very good condition, so that if blood

had not reached the hand gangrene must have followed. Bernheim says that no pulse could be felt below the site of the anastomosis and the success of the operation, from an operative standpoint, is in doubt.

I have found in the literature about 69 cases of arteriovenous anastomosis and agree with Bernheim and others that in the past the cases have not been selected with sufficient care. It is very evident that if the gangrenous area is very extensive it is useless to do an anastomosis in these cases, so the operation must be performed at the very earliest indication of a possibility of the extremity becoming gangrenous if we hope to have success.

Sixth vascular operation—Venovenous anastomosis. At the last German Surgical Congress Schaack and Hesse reported 23 cases of saphenofemoral anastomosis.

In 1906 Delbet advised a new operative procedure for a certain group of varices, which, by means of transplantation of the venasaphena into the venafemorals at a new place by vascular suture, produces normal physiological conditions for the venous blood circulation.

Schaack and Hesse to justify the performing of their operation examined 100 preparations of the femoral and saphenous veins in order to be sure of the location of the valves in each. It was found that the femoral veins always had at least one pair of valves below the mouth of a saphenous vein and, in 73 per cent., two or three, or even more, pairs of valves were present.

Prof. Delbet informed the authors by letter that 25 cases in his clinic have been operated on successfully. Of the 23 cases reported by Schaack and Hesse only one was unsuccessful. At the time of the operation 16 of the patients had ulcers of the leg. In every case the ulcers which had hitherto defied every treatment healed. They could also ascertain in all their cases a diminution and even repeatedly a complete disappearance of the varices. They state that the operation is indicated: (1st) for strong and otherwise healthy persons; (2nd) only in case of valvular insufficiency of the saphena; (3rd) the varices must be situated within the range of the vein saphena magna; (4th) their trunk must allow of free passage. Their report also gives the contraindications for the operations.

The conclusions which may be drawn from the resume of the cases which have been reported up to date might be classified as follows:

1. *Venesection is indicated:*

1. Broken compensation,
2. Threatened cerebral hemorrhage,
3. True plethora,
4. Croupous pneumonia,

5. Pulmonary edema,
6. Kidney diseases—acute uremia, etc.,
7. Chlorosis,
8. Poisoning—gas,
9. Sun stroke.

2. *Transfusion is indicated:*

1. Secondary anemia,
2. Pyemia,
3. Septicemia,
4. As a preliminary in an anemic patient who must undergo a severe operation.
5. Hemophilia,
6. Illuminating gas poisoning.

3. *Venous or Arterial Grafting is Indicated:*

1. After excision of aneurysm,
2. After excision of malignant tumor involving a large vessel,
3. If ends of a severed artery cannot be approximated and anastomosed,
4. Traumatic rupture of artery.

4. *Arterial End-to-end Anastomosis is Indicated:*

1. If ends of severed artery can be anastomosed.

5. *Arteriovenous Anastomosis is Indicated:*

1. Threatened gangrene of an extremity,
2. Embolism of an artery,
3. Traumatic rupture of artery—if grafting cannot be done,
4. Presenile gangrene—early,
5. Thrombosis of an artery.

6. *Venovenous Anastomosis is Indicated:*

1. Varices—due to insufficiency of the valves of the saphenous vein.

7. *Excision and Ligation of Veins is Indicated:*

1. Varices (whose extent is limited).

DISCUSSION.

W. C. Dugan: While I have done no work along this line, I have been very much interested in the subject. I realize, as we all do, that we are just at the beginning of some great work in vascular surgery. I think the instrument exhibited by the essayist will prove to be of great assistance in performing operations along this line.

I am glad to learn that pre-senile gangrene is not now so hopeless a condition as we have always considered it to be. I recently exhibited a case to this society in which I had done an amputation for pre-senile gangrene. This patient had the prodromal symptoms for a week, and had they been properly interpreted and anastomosis made, it is possible that the leg could have been saved. Of course, in senile gangrene, where the vascular changes are far advanced, we cannot hope for such good results.

I have enjoyed the paper very much, and I am glad that the doctor brought up this subject.

Jno. R. Wathen: I think the society is to be congratulated upon hearing such a paper as this. It is a pity that we do not have more papers of the kind.

Dr. Price has probably done more of this work than any one in the city. When I first began to advocate transfusion, he sent me a set of instruments, which I exhibited to this society and subsequently loaned to various members to use, and they have all gotten fairly good results. Personally, I have been disappointed in the results obtained, but I believe there is a great future for it. In the hands of such wonderfully skilled men as Drs. Carrell and Guthrie, of St. Louis, some very brilliant results have been obtained by

taking a kidney from one cat and transferring it to another. The transplanted kidney would functionate for a while, but later on it would undergo certain fibrous changes. On a number of occasions, both in this country and in Europe, the leg of one animal has been successfully anastomosed upon the leg of another animal. If I am not mistaken, I recently saw a picture in one of the German Journals, showing a dog resembling a pointer but having one leg like that of a setter which had been transferred from another dog.

J. Rowan Morrison: Just a few words in connection with the first part of the paper. I believe there are many instances where a great deal of benefit can be obtained by proper bleeding at the right time. I have tried it in a number of cases of failing compensation, as mentioned by the essayist, where the right heart is overburdened and cannot do the work. Under such circumstances, the withdrawal of 16 to 24 ounces of blood will relieve the circulation, make it much more brisk, and bring about a condition that we could not obtain by the administration of medicines in so short a time. In cases of uremia, the effects of thorough bleeding are sometimes remarkable. I can recall three patients with slight kidney disease, who were not really uremic but were very drowsy from extreme plethora, and in all of these cases bleeding gave brilliant results. Therefore, I am heartily in favor of bleeding if it is done at the right time. Before the patient has gone too far, and I am sure that in many instances we can get results from it that could not be obtained in any other way.

John W. Price, (Closing): I wish to thank the gentlemen for their kind reception of the paper.

Blood vessel surgery is often very difficult. Men who write on this subject all say that practice, and more practice, and then more practice is the only way to attain success in this line of surgery. Furthermore, it seems that a degree of asepsis that would suffice for abdominal surgery is not at all sufficient in this work; that very often infection will develop of which there is no evidence macroscopically, but which will result in the formation of a thrombus. The three chief causes of failure in doing blood vessel anastomosis are, (1) thrombus; (2) constriction, or narrowing of the lumen of the vessels at the site of anastomosis, and (3) leakage. Nowadays few men have any difficulty from leakage; thrombus is responsible for most of the failures.

The cases reported by Schenk and Hesse are perfectly remarkable. In 48 cases of persistent chronic leg ulcer with varicose veins, they successfully did venovenous anastomosis without any bad results except in one case, in which blood poisoning developed, which they attributed to faulty asepsis.

The work that Bernheim has done is, I think, going to give surgery in beginning gangrene a

very strong push forward. The results in cases in which he transplanted a vein to the popliteal artery were, I think, marvelous.

I wish to apologize for having taken up so much time in reporting cases of other men; I am sorry that I have not more cases of my own to report, but I considered that the best way to deal with this subject was to make a full report of all the work that has been done, assuming that many of you, like myself, have not been familiar with what has been done along this line.

WHOOPIING COUGH.

(PERTUSSIS.)

By H. L. RAPP, Louisville.

This subject is so old and well known, that I have tried to make this paper as short as possible. It does not deserve the title of an essay. The only thing that I might suggest as new, may be something in the way of a prophylactic treatment. In writing this paper I have referred to such works as Roth, Holt, Tyson, Hare, Sajous, and others. The older books give about the same information as the newer ones, with the exception that the older works, in speaking of the cause of the disease, say that it is *probably* caused by some micro-organism, while the newer ones, namely, Sajous, describe the character and nature of the germ, likely to be the cause of whooping cough.

Whooping cough is an infectious and contagious disease, characterized by spells of coughing, accompanied by a long drawn inspiration, producing the peculiar sound or whoop.

It is a question, as to whether this disease was known to the Greeks. Hippocrates and Galen, in their writings speak of a disease similar to whooping cough. It was known as a distinct disease in the sixteenth century.

ETIOLOGY.

It is caused by specific bacteria. Ritter described, as being likely the cause, *diplococcus tussis convulsivae*. Arnhelm attributed it to a bacillus resembling that of influenza. But that minute bacteria recently discovered by Bordet and Gangon, French bacteriologists, seem likely to be the real cause of whooping cough. Owing to the irritating character of its toxin, it causes violent local irritation and reflex cough. It proves extremely irritating when applied locally. When injected into the eye of a dog, it caused the cornea to become white and opaque. While it affects persons of all ages, children are most susceptible, perhaps because of most adults having had the disease during childhood, though we often find adults who have never had the disease, and still seem to be immune. One attack usually

confers life-time immunity, though some books speak of relapses. It is more serious in older persons, and in very young infants. The epidemics are more common in spring and winter and often precede and follow measles or scarlet fever.

There is no morbid anatomy peculiar to whooping cough. The peculiar states found after death, are due to complications, bronchitis, pneumonia, emphysema, etc.

SYMPTOMS.

Whooping cough has a period of incubation of from seven to ten days. The cough in the beginning is in no way peculiar, like an ordinary bronchitis with slight fever. This may go on for about two weeks, and without history of contagion, whooping cough may not be suspected. After this time the cough gradually gets worse, especially at night and occurring in paroxysms or spells, a number of short convulsion coughs, followed by a quick deep inspiration, producing the peculiar sound or whoop, then more cough, this being repeated a number of times, until finally a small amount of thick mucus is expectorated or thrown out by vomiting, which often occurs in these spells. During these attacks the child is often helpless, needs assistance, the face becomes red or blue and swollen. After the attack the child complains of pains in the sides of chest, due to effort in coughing and is so tired out that it will sometimes lie down. In milder cases immediately after the coughing spell the child resumes its play. They can tell when a spell is coming on, and often run to a place to expectorate or vomit, or call for assistance a moment or two before the spell comes on.

The paroxysmal stage, if uncomplicated, usually has no fever, nor peculiar physical signs in the chest, perhaps a few moist rales. This stage lasts from four to six weeks, mild cases may be shorter.

In the stage of convalescence, which lasts perhaps four weeks, the paroxysms become milder, less frequent, the vomiting ceases, the appetite returns, the child gets more rest at night and becomes normal in appearance. So in all, whooping cough may last from 10 to 12 weeks or three months.

COMPLICATIONS AND SEQUELA.

The most frequent complications are bronchitis, broncho-pneumonia, pleurisy, collapse of lung, and interstitial emphysema. During the paroxysms hemorrhage may occur in the conjunctiva, nose, and in the brain, may produce convulsions, paralysis or death. Perhaps in very young infants, permanent deformity of chest, chicken breasted. Tuberculosis may be a remote complication.

PROGNOSIS.

This is usually good, the danger lies in the complication, especially broncho-pneumonia. The younger the child the more danger. Also bad in poorly nourished or rachitic children.

Diagnosis can hardly be much without the appearance of the whoop, unless one have the history of contagion.

TREATMENT.

We have no specific remedy for this disease. The child should be placed in the best hygienic surroundings, plenty of fresh air. Cases that are not complicated, may be taken out of doors in pleasant weather, but the street cars, theatres, picture-shows, etc., should be avoided on account of the danger of contagion to others. In the parks, they should be kept away from other children, who are not afflicted with the disease.

Good nutrition is very important as the child often becomes very much emaciated, on account of the frequent vomiting. It is well to give a little milk after each spell of vomiting, as it may be then absorbed before another paroxysm comes on. Among the drugs that are used, I believe belladonna and the bromides are the most useful, they seem to lessen the number and severity of the paroxysms. Syrup of chestnut leaves is a household remedy, and may at least be used as a vehicle, for administering other remedies. Ammon. acet and pot. iodide are also used.

Aconite and veratrum viride are recommended when the vascular engorgement is excessive or when there is danger of hemorrhage, as in the brain, etc., but these drugs must be used with great caution.

Henbane or hyoscyamus is sometimes used instead of belladonna, but is more of a narcotic and not as well borne by children as belladonna.

Quinine is recommended by some. By stimulating the adrenal system and sympathetic center, it increases the propulsive activity of the arterioles and thus augments the proportion of blood, rich in auto-antitoxine into the capillaries. But this is all theoretical.

Amyl nitrite and chloroform are recommended during the paroxysms. Only two or three drops of amyl nitrite and only a few whiffs of chloroform, are to be used. I have never found it necessary to use them.

Bromoform CHBr_3 which is similar to chloroform in chemical composition, except that Br. has been substituted for Cl., has been used but has fallen into disuse. It was not given by inhalation but given internally, two to five drops in elixir.

Antipyrine and chloral hydrate, lessen the sensitiveness of the mucous membranes, but are dangerous to children. Monobromated

camphor has been used but is a gastric irritant.

Heroin combined with terpin hydrate and even opium can be used carefully to give the patient a little rest at night. Various sprays as, for instance, resorein, has been used, but with little or no effect.

A small amount of kresoline vaporized in the room now and then seems to give some relief.

A WIDE BELT.

Experiments are now being made with a vaccine against whooping cough, it is not yet on the market for sale. Cultures of a germ, thought to be the cause of whooping cough (the germ discovered by Bordet and Gagnon) sterilized and put into tubes, each containing 20 million bacteria to each 1 c.c.

During last February three of my own children were suffering with whooping cough, when a new baby was born to us, the birth taking place at a local infirmary. Knowing that whooping cough in a baby so young was a very dangerous condition, on account of the complication and sequelae that might result, I was thinking of how I could protect the little one, when Dr. Phil Barbour suggested that I make use of the vaccine.

I wrote for some of it, and Parke Davis & Co., through their representative, Dr. Bolling, was kind enough to furnish me with a supply. He explained to me as yet it was only used experimentally, and that it had never been used (to his knowledge) in a baby so young, and that he could not promise that there would be no reaction, or how much the reaction would be. Being between two dangers I decided to use the vaccine and begin with a small dose.

The baby weighed seven pounds. When nine days old I injected 1-2 c.c. There being no reaction after a week, I injected 1 c.c., being the contents of a whole tube and represented 20 million dead bacteria, which was followed by no reaction whatever. The baby is now two months old and has never shown any symptoms of whooping cough.

Now the baby is partly nursed on the breast and partly on the bottle. It may be that some immunity was conferred to the baby from the mother, through the breast milk.

In another case, a baby three months old contracted whooping cough from a little brother and sister. This baby being entirely on breast milk. No vaccine was used in this case, as it was not reported to me until late in the disease.

Another baby, six months old, was just beginning with whooping cough. I at once suggested the use of the vaccine but the family objected to its use. Not knowing whether to expect more reaction in a child that was al-

ready infected than in one where there was no infection, I did not insist on using it, especially since they were not in favor of it.

I would like to hear in the discussion, whether there would probably be more reaction in a person infected than in one not infected.

I did not use it on my older children since Dr. Bolling thought it useless in far advanced cases.

I am sorry that I did not have the opportunity to use it in more cases before writing this paper. But it goes to show, at least in this one case, that it was harmless even in a baby so young. So I think there is room for more experiments.

DISCUSSION.

Harry A. Davidson: I simply wish to refer to the treatment. At the Kentucky Children's Home, during a recent epidemic of whooping-cough, I used the pertussis vaccine in about 25 cases. I have also used it in a few private cases, and I am inclined to think that we have found almost a specific for pertussis. I have given it in all stages of the disease and also as a prophylactic. I have given it to babies a few days old, to girls 17 to 19 years old, and in all intermediate ages. Of course, in the young babies, it was given as a prophylactic, because there was whooping-cough throughout the whole building and they were exposed to it constantly. Several of these babies did not develop pertussis after receiving the vaccine. A number of the children received the vaccine as soon as diagnosis was made; that is, as soon as they began to whoop, some ten days or two weeks after the onset of the attack. Some of these children ceased whooping almost immediately—within twelve to twenty-four hours.

In his paper the essayist mentioned the great danger of broncho-pneumonia as a complication of pertussis. Before the use of the vaccine was begun, several cases of broncho-pneumonia had developed and, of course, the administration of vaccine did these patients no good. Holt claims that the mortality from broncho-pneumonia following whooping-cough is from 70 to 80 per cent. While we lost a few children at the Home, our mortality was nothing like that figure. We had several cases of broncho-pneumonia that got well.

As I understand it, the use of the pertussis vaccine is still in the experimental stage and it has not yet been put upon the market; but, after having tried it in 25 or 30 cases, I feel that it is almost a specific in this condition.

Dr. Rapp did not mention one drug which I have used in a great many cases of pertussis; namely, calcium sulphid. Dr. Barbour and I have used this agent for many years, and we have thought that we have secured better results from it than from any other remedy. We simply sat-

urate the child with calcium sulphid and, as a rule, with excellent results. It does not stop the whoop but it considerably lessens the number of paroxysms.

I wish to thank the essayist for his very able paper.

Wm. A. Jenkins: So far as the treatment is concerned, I have been watching very closely the reports made by Dr. Davidson and others in connection with the use of pertussis vaccine, and it seems to me that we are going to have in this vaccine an ideal treatment for whooping-cough.

I wish to make just one or two points in connection with this subject. If the vaccine treatment does not prove to be what is expected of it, our hope must continue to lie in the employment of such remedies as will tend to shorten the paroxysms and decrease their severity, for therein lies the danger—not only the danger of extension of the infection, and from vomiting, thus keeping the patient from obtaining sufficient nourishment, but also from the damage which may be done to the pulmonary structures. Any one who has ever seen a child in a paroxysm of whooping-cough, knows the great strain to which the pulmonary mechanism is subjected, and we should do everything we can to lessen this and preserve the lungs so that their further growth and development may not be impaired. The elastic and muscular elements of these structures are so injured by the attack that the lung loses its tone, thus rendering the patient more liable to ordinary infections with which they are unable to cope as well as they were before being subjected to this weakening influence.

I think the essayist mentioned most of the remedies in use at the present time. I disagree with him in regard to the use of antipyrin. All of the recent text-books favor the use of this agent. It should be given in minute doses, every few hours, in syrup of chestnut leaves—not because the latter is a "household remedy," but because I believe there is really some virtue in the leaves of the chestnut tree. A syrup of these leaves, made with brown sugar, and fed to the child in teaspoonful doses, every few hours, makes an excellent vehicle for minute amounts of belladonna, antipyrin and some salt of opium, such as sulphate or phosphate of codein, and will tend to decrease the severity and frequency of the paroxysms and thus, in a measure, do away with the strain on the elastic and muscular elements of the pulmonary structures.

Bernard J. O'Connor: I believe that we have all had the same experience in the treatment of whooping-cough, and that each of us has his favorite drug, differing with the individual. Personally, in a little epidemic in my own family, I secured very remarkable results from one of the oil of thyme preparations. It apparently not only lessened the number of paroxysms, but it had an astonishing effect upon the children's appetites. The vomiting decreased to a marked ex-

tent, and the children ate twice as much after taking it as before. The children showed an average gain in weight of five pounds during the course of the attack.

Pertussis is not rare in adults, but in the few cases that I have seen there was no "whoop". In my own family, I am sure that the children acquired the disease from a servant girl, about 40 years of age, who for some weeks had been troubled with a very distressing cough, and shortly afterwards the children developed whooping-cough.

I am exceedingly glad to hear the favorable reports that have been made on the vaccine treatment of this condition. If other investigators are able to corroborate the experiences of Dr. Davidson and Dr. Rapp, it would appear that we have a specific for the treatment of whooping-cough.

Just one point in regard to the use of vaccines as a prophylactic measure. I think too much is being said about the so-called negative phase. If you have read the recent literature in connection with vaccine therapy, especially in typhoid fever, you will have noticed that, in the dozen or so of cases that have been reported, where typhoid fever was acquired just at the time the vaccine was administered, the disease ran a very mild course, the average duration being something like two weeks. Therefore, I see no reason why, in any institution, where an epidemic is just starting, or even when it has reached fair proportions, vaccine should not be administered. The use of the vaccine should be begun as early as possible; there is no use of giving any kind of medicine when a patient is dying. The use of an appropriate vaccine early in any infection, will most likely give good results.

Oscar W. Doyle: I have been very much interested in the report made by Dr. Davidson in regard to the use of pertussis vaccine. When a man of his calibre makes the statements that he has made, we can come very near saying that we have a specific for this condition.

A few remedies that I have used with good results have not been mentioned. One of these is oil of eucalyptus, and another of iodide of calcium. I have had better results from the iodid than from the sulphate. I have used it in all cough conditions in children with splendid results. An emulsion made with oil of eucalyptus will decrease the frequency and severity of the paroxysms to a marked degree, and I have discarded all other remedies in cough conditions in children.

P. Richard Taylor: One of the speakers mentioned the infrequency of whooping-cough in adults. During an epidemic which occurred in this city in the spring of 1911, I saw a great many cases, one of them a man 65 years of age, who came to me for trouble with the throat, and in which I made diagnosis of whooping-cough; in fact, I had it myself for three weeks before I

knew what was the matter. In my own case the paroxysms were so terrible that I was almost afraid to go to sleep, and when I felt an attack coming on I would try to get hold of something; or, if nothing was available to hold to, I would pick out an easy place to fall and get down on my knees and choke and choke until the paroxysm ended. A local physician brought his brother to me, and said that he had some trouble with his throat, characterized by choking spells. I had a great many such cases, and of course I referred them to their respective family physicians for treatment. If the condition is as bad in children as it is in adults, judging from my own experience, we need some efficient remedy and we need it badly. In my own case I ruptured a blood vessel in the conjunctiva in each of my eyes. In stooping over and coughing, all the air would be expelled from my lungs and I would not have any when I straightened up, and that is one of the most distressing conditions that I know of.

A. W. Nickell: I am glad to hear such a free discussion to-night among the internists of a subject which is of such vital importance as whooping-cough. It is interesting to look back over the history of this affection from the time that Danz wrote his first monograph in 1791. Berger reports one case in a woman 57 years of age; Heberden reports a case of whooping-cough in a woman of 70 and another in a man of 80 years old.

I wish to particularly speak of the complications of pertussis. I hope I will not be considered too radical when I say that a disease of this kind should be placed in the category, so far as the mortality is concerned, with diphtheria and scarlet fever. It is not the disease per se that kills by the dissemination of toxins, as in diphtheria and scarlet fever, but it is by the complications which follow in its wake, which, during the winter months, is most frequently broncho-pneumonia, and in the summer months, gastro-enteric diseases. Again, it very frequently causes malnutrition, which renders the patient more susceptible to intercurrent disease, tuberculosis frequently following a prolonged attack of this malady.

While doing postgraduate work in New York, a while ago, I had the pleasure of being associated with Jacobi, and of working with Kerley, who has long been associated with Holt. Dr. Davidson spoke of Holt's mortality statistics being between 70 and 80 per cent., but I think that is an error. In founding asylums and hospitals for infants, in some epidemics, he gives a mortality as high as 50 per cent. A disease so grave as this requires more thought and consideration than we have been in the habit of giving it. On one occasion, an epidemic broke out in the country branch of the New York Infant Asylum, and we had constantly under quarantine a large number of cases. As fast as one case would be discharged, another would contract the disease. During

this epidemic we tried out practically every form of treatment known. The cases as they developed were divided, for study, into groups of 20, and allowed to run along without any treatment at all until they reached the height of the paroxysmal stage, which was something like from ten to fourteen days after the initial symptoms. Then a careful record was kept, day and night of the number and severity of the paroxysms, and after they had gone along for three days without any change in severity, we believed the height of the paroxysmal stage had been reached, and it was then considered to be time for medication, which consisted in the use of insufflations and inhalations, followed by internal administrations. In six cases we practiced direct insufflation with bicarbonate of soda, boric acid and resorcin, but after using this for three days without any benefit, it was discontinued. Then we tried inhalations medicated with wine of ipecac, with beechwood creosote and with turpentine, from which we obtained very excellent results. For internal medication the drugs selected were, alum, fluid extract of horse chestnut leaves, dilute nitric acid, hydrochlorate of cocaine, bromoform, quinin, the bromides, belladonna and antipyrin. We tried the fluid extract of horse chestnut leaves and got practically no results. We tried 40 cases with alum, which was of some service, but badly borne by the stomach. Bromoform was useful in a small percentage of cases only. We treated a number of cases with dilute nitric acid and got no results from that. Cocaine possessed some value in controlling the paroxysms, but the results were not sufficiently marked to warrant its further use. Some benefit was derived from quinin, but its administration was attended with difficulty. Then we took up belladonna, and in 60 cases in which we used it to the point of physiological effect, for from five to seven days, no results were obtained except in three cases. Then we began the use of the bromides, using doses of equal amounts of the bromides of soda, potassium and ammonium, which, when given in syrup of raspberry, on a full stomach, from all standpoints, accomplished the best results of any treatment thus far given, and was attended by very little, if any, stomach disturbance. Then antipyrin was used in 60 institutional cases, was readily taken and easily borne by the stomach—two very desirable requirements; is not depressing when administered with any degree of intelligence, and produced the most beneficial effects of any drug given alone, the bromides taking second place. The two were then combined and used in a number of institutional cases, and more effectually controlled the disease than when either was given alone, our doses being given, for instance, in a child from 8 months to 1 year of age, 1-2 grain of antipyrin and two grains of bromide of sodium, every two hours, giving six doses in 24 hours, in

the exipient above mentioned. This combined treatment was subsequently tried in about 600 cases at the infant asylum, the out-patient department of the Babies' Hospital, and in private practice, with the most gratifying results.

I have had no experience with the pertussis vaccine, but hope it will prove to be of value.

H. L. Rapp, (Closing): I have enjoyed the discussion of this paper very much. I did not know that Dr. Davidson had been using the pertussis vaccine until a few days ago, and I am glad to have heard his report. From what I understand, it is a perfectly safe thing to use in children, as there is no reaction whatever.

I am afraid to give antipyrin to a child unless a trained nurse is in attendance to give it proper attention in case it should become blue, as sometimes happens. Codein may be of some benefit in these cases. Heroin is dangerous. I have never had any experience with oil of thyme, but think it may possibly be of value. It is recommended by many.

I was told by one old darkey not long ago that mare's milk was a sure cure for whooping-cough, and in the case where they refused to allow the vaccine to be used, they said they had a mare and would obtain some of its milk, but they never reported to me whether they used it or not. Another old-time remedy is to take these children to the gas-works and let them inhale the fumes. One family showed me a tin bucket containing some slack from burned coal, and said that they simply put hot water on it and allowed the child to inhale the fumes. It smelled just like tar, and it is possible that it contained coal-tar products which may have had a sedative effect.

Constipation in Children.—Perier and Ganjoux discuss the symptomatic importance of constipation from obstruction, from modification of the contents of the intestines and from defective action of the expelling muscular fibres or nerve plexuses innervating the intestine. Search for the cause along one of these three lines will clear up many puzzling syndromes. Constipation in the mother, especially from lack of out-door exercise, is a frequent factor in the constipation of infants. Congenital stenosis of the rectum may escape discovery for several weeks or months.

Resection of Orbit to Relieve Exophthalmos.—Dollinger reports with illustrations a case of exophthalmos so severe that the cornea of the left eye became ulcerated and the patient, a man of 62, suffered from intense pain in the eyes and head, rebellious even to morphine. There were no other symptoms of Basedow's disease. By resecting the wedge from the outer wall of the orbit, the eye-ball sank more to the side, relieving the forward protrusion and enabling the lids to close over the cornea. The pains subsided and the corneal ulcer soon healed.

CLINICAL CASES.

EXHIBITION OF SPECIMENS.

By GEO. A. HENDON, Louisville.

I.

PAPILLOMATOUS CYST OF THE OVARY.

The first specimen is a papillomatous cyst, involving both ovaries, with an independent cyst, covered with papillomatous growths, which was wedged down into the culdesac, and which, upon examination of various sections taken from different portions of the tumor, exhibited malignant structures.

This case was operated upon about two years ago, and there has been no evidence of recurrence since operation.

II.

EPITHELIOMA OF THE SUB-MAXILLARY GLAND.

This patient, a man, was operated upon six months ago by a local surgeon for epithelioma of the lip. Recently he came to me with a well-defined enlargement of the submaxillary gland. This was removed by complete dissection, making the well-known Crile incision on three sides, turning the flap back and clearing out the cervical triangle. None of the glands were enlarged except the submaxillary which I have here. June 1st: this patient has since died.

III.

CAULIFLOWER EPITHELIOMA OF THE CERVIX.

This was removed by the vaginal route, by excision and actual cautery. The patient returned, in three or four months, with a recurrence of the growth, and a secondary operation was performed.

Since that time she has gone along and gained very much in weight, now weighing 153 pounds, which she tells me is about 20 pounds more than she has ever weighed. Of course, the time has been too short to make any definite statement as to the outcome of this case, but she is well, so far as she knows, is able to attend to her work and has gained in weight. This growth was removed by first excising the cauliflower material, then packing the vagina with iodoform and using an ordinary tinner's soldering-iron to cauterize. The discoloration, I presume, was brought about by the vaginal secretions.

The second growth is, as you see, considerably different from the first, both in size and appearance, but both have been carefully examined, sections being taken from different portions of the growths, and their epitheliomatous character demonstrated. In the second operation, in removing the tumor, which was situated on the posterior portion of the

cervix that had been left, we cut very wide and got into the peritoneal cavity, but no trouble followed and the patient made a very nice recovery. June 1st. This patient is still well.

IV.

EPITHELIOMA DEVELOPING FROM A NAEVUS.

The photograph which I herewith exhibit, shows the site of the naevus from which this tumor developed. The patient first noticed signs of irritation in the birth-mark in 1895. Since that date the growth had gradually become larger until he finally sought relief on account of the hemorrhage which occurred. This growth was also removed by first excising the mass and then using soldering irons to cauterize. There was considerable metastatic involvement, extending up into the axillary space and down into the inguinal region. Therefore, I presume that marked benefit cannot be expected; that the removal of this mass of tissue is simply palliative. June 1st. He has since died.

V.

SARCOMA OF THE HIP-JOINT.

This tumor had existed since last June, when the patient was seized with pain in the hip and, as is natural in such cases, there being no swelling, it was attributed to sciatic rheumatism and the patient was so treated. He was brought to me from a distance in January of this year. I made an incision and was able to remove this tumor from the femur. It had destroyed the periosteum and caused a pseudo-paralysis of the femur. I did not deem it wise to attempt to do a hip-joint operation, because these cases generally die. This has been admirably and completely worked out by Bloodgood, who has shown that as good results are to be obtained from excision or resection as from amputation.

VI.

APPENDICES.

This is an appendix which was removed as an incident to an operation for the removal of an ovarian cyst about the size of an orange. One very important feature in connection with this cyst is that it attracts attention by causing a great deal of uterine hemorrhage. This patient had been cured a number of times on account of the hemorrhage she had during her periods. At operation it was found that she had an ovarian cyst about the size of an orange. On one occasion, while attending one of Dr. Murphy's clinics, I saw him remove a similar growth and he laid great stress upon the production of hemorrhage.

During the operation we encountered this appendix. The patient had never shown any signs of appendicitis. It is interesting to

note that the organ has become completely solidified with fecal concretions.

These other appendices I exhibit because one appendix always looks lonely by itself.

These cases are reported merely to illustrate some of the phases of malignancy as we meet it in our daily work.

DISCUSSION.

J. Garland Sherrill: I would like for Dr. Hendon to explain whether he means that these patients die primarily from the operation, or secondarily.

G. A. Hendon: These patients usually die very promptly after operation. Very few recover from disarticulation of the hip joint. I suppose the reason is that, generally, when they come to operation they are very much depreciated in health by the cancerous cachexia, and are, therefore, unable to stand the shock of extensive surgical procedure. If they could be gotten early, no doubt the operative recovery would be as good as in other conditions.

Wm. H. Wathen: I wish to speak of only one of the cases reported by Dr. Hendon; that is, the cauliflower epithelioma of the cervix. This is the most amenable to treatment of all forms of cancer of the uterus, if operated upon at all timely. I operated upon a woman, twenty years ago, removing a cauliflower mass larger than this, and then removing the uterus per vaginam, and this patient has not had any trouble since the operation. I do not understand why Dr. Hendon did not remove the uterus. That is the only way to obtain the utmost security against the return of the trouble. From what he says, I feel reasonably certain that, had he removed the uterus, the chances would have been in favor of a permanent recovery, but it is not probable that she will recover after the amputation of the cervix, done at the second operation, and if she has another recurrence it will probably extend so far up into the structures that a radical operation will not do the good it would have done at first.

J. Garland Sherrill: Just one point in connection with the case of sarcoma of the femur. I cannot agree with Dr. Hendon that all cases of hip amputation die operative deaths. I have never lost a patient from amputation of the hip joint in my life, and I know of a number of other surgeons who have had a similar experience. I do not believe that a man in fair health should die from a hip amputation, provided it is a clean case, without any pus. In my opinion, the mortality from hip-joint amputation should be about two or three per cent.

In regard to recurrence, I believe that in nearly all of these cases there is recurrence followed by death. I showed a patient to this society fourteen days after amputation of the hip joint for sarcoma, involving the knee. I think Dr. Hendon saw that patient. He died within a year,

from recurrence in both forearms, in the abdomen near the stump, and in the opposite leg.

G. A. Hendon, (Closing): In reply to Dr. Wathen, I will say that every case demands special consideration. My surgical judgment—which in all of us is partly instinct, and we cannot explain how much of it is good nor how much is bad, in this case was all against total hysterectomy; I did not think the patient would be able to stand it.

REPORT OF CASES.

By E. S. ALLEN, Louisville.

CASE I.

OPERATION UNDER LOCAL ANESTHETIC FOR PERFORATED GASTRIC ULCER.

(REPORT OF CASE.)

In the early part of January this patient was brought here from the country with the following history:

Male; white; age between 45 and 50; had suffered for a number of years with what he termed "stomach trouble," and had been treated along this line with only temporary relief. His attacks of late had become more frequent and more severe. His family physician, believing that he had some gallbladder involvement, brought him to this city for operation. He came under my care on Sunday afternoon, January 7th, giving the following recent history: On the preceding Wednesday, at about five o'clock in the morning, he had been seized with intense pain in the right upper abdomen. His physician was called and, finding him in extreme pain, gave him 1-4 grain of morphine. In half an hour he had to repeat the hypodermic, without relief. In an hour another hypodermic was given, the patient getting some relief. The patient was more or less under the influence of morphine, with little relief, until Sunday at 5:00 P. M., when I saw him. His condition was serious; pulse 160; temperature 98; anxious expression; abdomen distended and very sensitive, especially over the gallbladder region; in fact, he came to me with a diagnosis of gallbladder trouble. He was vomiting frequently, a brownish fluid from the upper small bowel. He had not taken nourishment since the attack until the morning he left home, when he drank a glass of buttermilk. He had received several doses of castor oil since Wednesday. From the history of the case I suspected a perforated gastric ulcer with peritonitis, but was somewhat in doubt as to the correctness of the diagnosis from the fact that, 20 minutes before he was placed on the operating table he vomited a quart of fluid, and the extreme tenderness over the gallbladder region, and the radiating pain to

ward the right shoulder, made me consider a perforated gallbladder. One thing I felt sure of was that, at least, I was dealing with a peritonitis. On account of his poor heart action we felt that a general anesthetic was not advisable. I informed the patient that his condition was serious. He realized this and asked that we operate on him. A one per cent. solution of quinin and urea hydrochloride was injected into the skin over the gallbladder region and infiltrated into the deeper structures, trying to infiltrate to the peritoneum. After waiting 15 minutes the skin incision was made, the patient stating that he did not experience any pain whatever. With a very sharp knife I incised the fascia, separated the muscles, picked up the peritoneum and incised it. I again asked the patient if I was giving him any pain; he stated that he did not feel any. When the cavity was opened a large amount of oily material was seen floating on the peritoneal fluid. It struck me that I might be dealing with a pancreatitis and that this oil was fat digestion; but the odor of castor oil was soon recognized. At least a tablespoonful of castor oil could have been dipped up. There were also some milk curds floating on the peritoneal fluid. The gallbladder was examined and found to be red and engorged, but not enough pathology existed to account for the peritoneal picture. The stomach was then pulled down and a large perforating ulcer presented in the field, located on the anterior surface of the stomach, about two inches from the pylorus. The patient said that he felt some pain when I pulled on the stomach. On account of the patient's condition I did not attempt to excise the ulcer, but with a purse-string suture I inverted it and then closed over with peritoneal sutures. Still no pain. I then closed with through and through silk-worm gut, having instituted drainage. The patient came off the table with apparently as good a pulse as when we started. He was placed in the Fowler position and proctoclysis instituted. The following morning the patient's pulse was 140; physiognomy apparently better; had slept some during the night. Temperature 100. For the next forty-eight hours I entertained some hope for his recovery, but on the following Wednesday morning he began vomiting, and, despite gastric lavage and hypodermoclysis, died on Wednesday afternoon.

I report this case merely because of the fact that the patient experienced practically no pain during the operation. I have, on several occasions, done minor operations under local anesthesia with quinin and urea hydrochloride, and once removed a fibroid tumor of the parotid gland with satisfactory results. In looking up the subject, I find that several strangulated herniae in individuals who

would not take a general anesthetic, had been successfully operated upon under this local anesthetic. Empyema of the gallbladder and appendiceal abscesses have been successfully dealt with in cases where the weakened condition of the patient precluded a general anesthetic. Dr. Green, of this city, reports several fissure and hemorrhoid cases operated upon under quinin and urea. The only objectionable features that I find mentioned are, the 15 or 20 minutes wait for anesthesia, and the induration which persists for as long as two or three months. However, this seems to occur only when solutions stronger than 1 per cent. are used. Some claim delayed union following the use of strong solutions.

CASE II.

Recently I was called to the country to operate for an abdominal tumor, in a man. I suggested to the family physician that the man be brought to the city, but he stated that the patient was not willing to come, and he did not think he was strong enough physically to stand the trip, as he was vomiting. I went out, prepared to operate, and found a man, 68 years of age, with a tumor extending to above the umbilicus. He gave a history of having had this tumor for eighteen months or more, always remaining about the same size. He had been working whenever he could, but could not bend over, being compelled to get down on his knees when he wanted to pick up something. I asked about his urine and he said that he had to get up several times every night to void, which took some little time. I examined him per rectum and found that he had a very large prostate gland. I suspected that this tumor was a distended bladder, but did not have a catheter with me. He was suffering no inconvenience at the time, but had had a vomiting spell two days previous. I advised him that it would be best to come to the city and let me observe him over a longer period of time, and ascertain the condition of his heart, kidneys, etc. He consented and came here. After getting him to the hospital

I had him void urine, and then introduced a catheter and drew off fifty ounces of perfectly clear urine. Upon microscopical examination not a pus cell could be found. From the history he gives, I believe that he had retained from forty to fifty ounces of urine in his bladder for a period of eighteen months, merely voiding what the muscular pressure forced it out. He was kept in the hospital and the accumulation of urine was drained out every two or three hours, trying in this way to restore the tone of the bladder, at the same time giving him large doses of urotropin to stimulate elimination, after which I did a perineal prostatectomy. The central lobe of the prostate was very large and obstructive, these

smaller portions sticking up high in the urethra and producing complete obstruction.

I report this case merely because of the large amount of urine retained for so long a time, leading to a mistaken diagnosis of fibroid tumor when it was merely retention of urine produced by this enlarged prostate.

DISCUSSION.

J. Hunter Peak: I would like to ask Dr. Allen as well as others who have used urea in connection with quinin, what special effect the urea has. Several years ago, while living in the south, it became necessary to administer to myself on account of malarial poisoning. I soon found that I could not take quinin by the mouth, and it was suggested to me to take bichloride of quinin, dissolved in forty parts of warm water, and inject it hypodermically, and I remember that sometimes for fifteen or twenty days there would be no sensation in my limbs where the quinin had been injected. Therefore, I would like to know why the urea is added.

The second case is not an uncommon condition in these patients with large prostates. I remember being called to a neighboring town last summer to see a man, 72 years old, with an enlarged prostate and a distended bladder, just as in the case reported by Dr. Allen. This man had to use a catheter as long as he lived, as I was never able to get him in suitable condition for operation.

I remember another case of distended bladder in a woman who had been sent to the Infirmary for operation. I was called to operate, and upon catheterization between forty and fifty ounces of urine were obtained. She died of uremia two or three days later.

J. Garland Sherrill: The second case reported by Dr. Allen is rather unique. We frequently see cases in which the bladder takes care of a good deal of urine, but the unique feature in this case is the time that elapsed from the time that the tumor was first noticed until operation. I have myself operated upon a man whose bladder carried much more urine than this. This was a man 79 years of age, upon whom I did an emergency prostatectomy because of suppression of urine. His trouble had run along for two or three weeks. It is remarkable for how long a time the bladder will retain a great amount of fluid without rupture and without infection. One would think that, with this amount of fluid in the bladder for such a length of time, infection would almost certainly ensue. Had any instrumentation been employed during this period, he would probably have had infection of the bladder.

W. T. Bruner: I have had some experience with quinin and urea hydrochloride, and in some cases I like it better than cocaine as a local anesthetic. It is a very good thing in tonsillar operations for the reason that the anesthesia lasts

longer than that produced by cocaine. In tonsillar operations there is usually severe pain for some time after the effect of cocaine has worn off, while with quinin-urea the pain does not come on for a number of hours and is not as severe as when cocaine is used. Furthermore, quinin-urea is safer than cocaine. The first time I used this anesthetic was in the removal of a cystic tumor, about the size of the end of my little finger, from the outer canthus, which was accomplished without any pain whatever. I regard it as an improvement over the old method with cocaine, and I have been using it for several years in operations about the nose, throat and eye.

Herbert Bronner: I think one interesting feature in connection with the second case would be to watch and see how much restoration of bladder power this patient is going to have. Mr. Fenwick has shown that, in cases of stricture or enlarged prostate, the longer the retention has gone on, the less restoration of bladder power there will be. In stricture, it does not make any difference if we do produce an anatomical cure, the restoration of function will depend upon how long the bladder wall has been subjected to stretching. Dr. Allen's case is unique with respect to the length of time the retention had existed. We see cases every day where a man has a few ounces of residual urine, or complete retention for a day or two, but to have retention of such an amount as in this case, for months and months, is rather unusual, and to me it appears to be very doubtful whether this man will have restoration of bladder function.

E. S. Allen, (Closing): I have very little to say in closing. In regard to the first case, I will say that all during the operation I was talking to the man. He asked half a dozen questions, and during all the manipulation he did not once complain of pain. I thought that possibly some of this insensibility to pain was due to the man's extremely weak condition, but whenever I made any traction on the stomach he would flinch. I was surprised by the fact that he did not show any evidence of pain while I was cutting through the abdominal wall and parietal peritoneum, where we would naturally expect pain, as well as in handling the gallbladder.

I am sorry that I cannot answer Dr. Peak's question as to the part that urea plays in this anesthetic.

In regard to Dr. Brunner's remarks, as to the possibility of restoration of bladder function in the second case, I had thought of waiting a while, keeping the bladder empty, to see whether he would regain any muscular or physical control. However, it seems to me that, after removal of the prostate, keeping the bladder empty and occasionally filling it up to ascertain what amount of muscular control had developed, would play just as much part in securing restoration of blad-

der function as waiting a long period of time, with the frequent use of a catheter and running the risk of infection.

ANEURYSM.

(REPORT OF TWO CASES AND EXHIBITION OF SPECIMENS.)

By J. GARLAND SHERRILL, Louisville.

CASE I.

Patient, male; white; age 29; admitted to the City Hospital January 5th, 1912.

Family history free from cancer or tuberculosis.

Personal History: Had typhoid at the age of 16; brain fever (as he expressed it) at 17; rheumatism, 6 years ago; denies history of syphilis but says he was treated for iritis several years ago. Iritis was probably syphilitic. He took iodide of potash at that time and says he received some form of local treatment for the eye condition. I do not know how long he was under treatment nor if it was carried out with any degree of skill.

Present trouble began three years ago with pain in the abdomen and back, which has grown progressively worse. When he came to the hospital he gave a history of an exploratory laparotomy having been done on August 8th, 1811, by Dr. Leo Bloch, in an effort to clear up the diagnosis. The abdomen was closed on that occasion without any effort being made to treat the aneurysm. The pain complained of was of a continuous, jumping character, localized above the umbilicus. Upon inspection and palpation a pulsating tumor could be felt. The pulsation was extensive and very distinct. Upon auscultation, a distinct bruit was noticeable over the whole area of the tumor that we could make out on the abdominal wall.

Patient was operated upon January 8th, 1912, with a view of attempting to wire the aneurysmal sac, which was carried out. He made an uninterrupted convalescence, and on January 15th, was doing nicely, the pulsation having markedly decreased. The history, as given by Dr. Clark after that time, is that the symptoms continued to improve. This improvement I believe to have been partly due to rest in bed. He was kept constantly at rest subsequent to the operation, and the area over which the bruit could be heard considerably diminished.

The wiring was not quite as successful as I should have liked it to be. We got about 8 1-2 or 9 feet of wire into the sac. I first used a very small wire, which would not go through the needle very well. Then I took a larger sized wire, but could not force it in and discontinued it.

At the present time the tumor has decreased in size, the pulsation has diminished, and the bruit cannot be heard over quite as large an area as before the operation.

CASE II.

In the second case, which was in the same clinic at the City Hospital, I tried the compression method, and I believe it would have been successful but for the fact that the patient would not stand the pain. This patient had a popliteal aneurysm. He gave a clean family history. His personal history shows that he formerly used alcohol to excess. He is a colored man, 49 years of age. He denied a history of syphilis and I was unable to find any evidence of the disease. Has never been sick, except for the ordinary diseases of childhood, until the present trouble began. He came to the hospital on December 19th, 1911. Two weeks prior to this time he had noticed a small lump in the left popliteal space, which had grown progressively larger; no definite history of traumatism, although he thinks he strained his leg. Upon examination, a tumor, about the size of a duck's egg, with a distinct transmissible pulsation and bruit, could be readily made out, and I recommended that compression be tried. I have succeeded, by manual and bandage compression, in effecting a cure in four cases, but in this case it was abandoned because of the pain it caused. I was not present when pressure was started by relays of students, and evidently the young men were a little too anxious and applied too much pressure. It was then decided to try the next best form of treatment; namely, ligation of the femoral at the apex of Scarpa's triangle.

This was carried out on January 8th, but I understand, from the history given by the interne, that the limb was not put up in cotton until it had become entirely cold. It was then put up in cotton and a hot water bath applied. The leg began to get warm and in twelve hours had regained its normal temperature. The patient insisted upon leaving the hospital four days after the operation.

My experience has been that compression is the best and most simple method of effecting a cure of popliteal aneurysm. Ligation is a successful method, provided the tumor has not grown to such an extent as to produce oedema below the site of the aneurysm. If this is present, the coagulated blood remaining after ligation there may cause sufficient interference with the circulation below to render gangrene likely, in which event it would probably be best to do a Matas operation, or to excise the sac.

DISCUSSION.

Leo Bloch: I saw this patient early in the summer of 1911. Diagnosis was made and abdominal section performed and, from the size of the aneurysm and its location, wiring was deemed inadvisable. Statistics show that this operation entails considerable risk and the results are not always good. Furthermore, while under my care this man was a private patient and, of course, that makes quite a difference. We do not have as much control over a private patient as we do over those in a city institution. I did not think the operation was advisable at that time, so the wound was closed and the patient kept in bed for quite a length of time with considerable improvement. As long as he remained in bed he suffered no pain and gained in weight. Finally, he left the hospital and went to his home in the country, where he continued to improve as long as he remained quiet. Then he returned to the city and went to the hospital. Dr. Sherrill called me up and told me that he was going to operate, and invited me to witness it, which I was unable to do.

The man's condition now is not as good as when I last saw him; the growth is no smaller. I would suggest that a radiograph would show whether or not a clot has formed, but from the man's appearance he does not seem to have been benefited in any way.

I have had some experience with abdominal aneurysm, and wired one of them with very unhappy results. The patient became able to leave the hospital, but the aneurysm ruptured at the site of the wire. The wire was shoved over to the far side, and post mortem showed the rupture to have taken place on the far side of the aneurysm where the wire had caused a clot to form. However, in some cases, wiring is worthy of a trial, but statistics show that it is attended by a very high mortality. Before his present trouble began this man was a molder, and even if he does make a partial recovery he will never be able to resume his former occupation. I am glad to see some one who is willing to take a chance with operations of this kind.

W. D. Dugan: Just a word in regard to the introduction of wire in these cases. The doctor spoke of the wire entering the sac. I think that is one fault to be found with the introduction of wire; it is very important that it should be introduced in a certain way. The wire should be on a spool and the end should be fitted into a canula of the ordinary kind, such as we use in tapping a hydrocele in a baby. When the canula is introduced the blood will spurt out. The point you want to watch is to not get the wire kinked. It should be fed into the cavity in such a manner that it will assume a coiled position. If this is done the complication mentioned by Dr. Bloch will not occur. If you straighten the wire and pull the spring out of it, it will impinge against

the wall and kink up, and you will have simply a mass of wire inside the cavity instead of a perfect coil. Care should also be taken that the last portion of the wire likewise assumes a coiled position. I think that is the whole secret of the treatment of aneurysm by means of wiring.

In regard to the second case, I think the treatment employed by Dr. Sherrill is the best method to use in these cases. I want to go on record as opposing the Matas operation; I would use it in the presence of an acute aneurysm but in no other form. I go even further than Dr. Sherrill. He says he would employ the Matas operation where there is much oedema of the leg. I would not. Where the condition has existed for some time and collateral circulation has been established, there is no reason why we should resort to a major operation when a minor operation will serve the purpose; namely, ligation on the proximal side.

I agree with Dr. Sherrill in regard to either digital or instrumental compression. It is a very painful process to the patient and very tiresome to the operator. However, if the operator will suspend a bag of shot from his hand, thus getting the advantage of the weight of the shot in addition to the pressure of his fingers, it will, to a great extent, relieve the muscular tension.

J. Garland Sherrill, (Closing): One thing that is especially interesting about these cases is that I saw both of them on the same day.

In the case of the abdominal aneurysm, I do not believe this man is cured. I believe this aneurysm lies at the origin of the coeliac axis, and obliteration of that vessel would probably block the hepatic vessels and cause considerable discomfort, if not loss of life, therefore, the outlook is unpromising.

In regard to the operation itself, the wire that I first attempted to use was too fragile, and the second was too large; I had difficulty in getting it through the tube that was to carry it. Therefore, I put the wire directly through the opening made by the canula in the wall of the sac, and what I did get in was introduced without the aid of a canula.

I had the temerity on one occasion to wire a thoracic aneurysm, using a very small wire. Ten days later, after the patient had completely recovered from the operation, the aneurysm ruptured, but the rupture was into the oesophagus and not at the site of the puncture. Therefore, I believe there is very little danger of rupture at the site of the puncture.

The results of treatment of aneurysm in the thorax and abdominal cavity are not good at the present time. I think two cases are recorded, in one of which the patient lived 53 days after a ligature operation, and in the other, 39 days. One is reported by Keen and the other by a foreigner whose name I do not recall. The results of any form of treatment have not been good, but if we succeed in relieving one of these patients,

we have relieved a man who is otherwise absolutely condemned to death.

In regard to the second case, this man left the hospital four days after the operation, contrary to the advice of the attendant at the hospital and myself. However, I have seen him since and he is getting along very nicely.

BRONCHIO-PNEUMONIA WITH HEMATEMESIS.

By HARRY L. READ, Louisville.

Patient, M. J., aged 5 years. Was first seen by me on the morning of January 26, 1912. The family history showed no constitutional diseases, yet both parents are extremely nervous. Patient was seventh and last child born in the family. Other children of the family are all living and well, but are subject to colds, tonsillitis and bronchitis.

Previous history. Bottle-fed baby, during his second year was seriously ill with gastrointestinal disorders. Has had measles, whooping cough, and several attacks of tonsillitis.

Present condition. Inspection disclosed a rachitic child, large head, belly bulging and tumid, decayed teeth, coated tongue and foul breath. Examination of chest showed a bilateral broncho-pneumonia, both tonsils large and inflamed. Liver enlarged and abdomen very large and markedly tympanitic. An annoying cough and pain on pressure of right side of chest.

Pulse 130, respiration 26, temperature 102 degrees F. After prescribing for patient and before I left his bedside he vomited about one pint of dark clotted blood. I ordered one half teaspoonful of adrenalin solution, 1-1000 given him at once, and this dose to be repeated after each hemorrhage.

Gave two grains of calomel to be followed in four hours by an enema of normal saline solution.

About two p. m. the enema was given resulting in a large dark, bloody stool. Vomited about one-half pint of dark blood. I ordered papine to quiet and control cough. Pulse 154, respiration 40, temperature 103 degrees F.

Patient had five hemorrhages during first sixty hours of illness. Stools contained no blood after the fourth day. Pulse ranged from 120 to 160. Respirations from 24 to 50. Temperature from 102 to 104 degrees F.

I dismissed patient February 13th, 1912, nineteen days after he was taken ill.

Besides treatment previously mentioned he had a few doses of castor oil. Creosote carbonate, 5 drops in milk every four hours. Ammonia in syrup of wild cherry as expectorant cough mixture. Digitalis, strychnia

and brandy as heart stimulant. Syrup iodide of iron and glyco-phospho-calico as tonics. Plenty of fresh air and proper food.

DISCUSSION.

W. A. Jenkins: I think any physician who has had considerable clinical experience always approaches a case of lobular pneumonia with considerable trepidation, even when the circumstances are favorable, and his trepidation increases in direct ratio to the unfavorableness of the attending circumstances. There are several reasons for this. One is that bronchial pneumonia more commonly attacks debilitated children, whose vitality is very low—rachitic children, tuberculous children, those subject to some chronic infection, etc. The disease seems to have a sort of predilection for this type of children. There are, perhaps, one or two other factors. One, which I have mentioned to this society before, is that the vascular system of the child in infancy and the earlier period of life, is not stable; the muscular and elastic elements have not developed in proportion to the other organs of the body, and collapse and atelectatic conditions are apt to occur. Another reason is that this type of pneumonia, from the standpoint of bacteriology and physiology, produces a very different lesion to those produced by other types of pneumonia. A horizontal section of the involved area of the lung will show an inflammatory, infiltrating, exudative process, all the way through; it is not confined to the area of vessels and mucous membranes, but occurs in the bronchial walls and in the peri-bronchial structures, and even, perhaps, a small amount of infiltration between the visceral layer of the pleura and the bronchial mechanism. Again, we know that this process does not behave like an ordinary infection in that it does not wind up with so-called crisis; it is more like a chronic infection—better one day and worse the next, tending to drag along for some time, up and down, and sometimes two or three weeks elapse before the final event of recovery or death takes place. When we consider that, even in the experience of the best men, of the largest clinical experience, and especially where this disease is secondary, following diphtheria, whooping-cough or measles, 70 per cent. of these cases die, we begin to realize the gravity of the condition.

As to the management of this condition, we have no specifics. That, perhaps, is the reason why so many different plans of treatment are advocated by different observers. The treatment is essentially and necessarily symptomatic, but the earlier we begin on these symptoms the less likely we are to have complications and the more likely we are to bring the case to a good termination. All we can hope to do is to build up the patient's vitality and increase Nature's fighting forces. I have not much faith in local applica-

tions. I do believe, however, that a cotton-bating jacket is a very desirable thing. I do not think much is to be gained from expectorant mixtures, as these are generally understood. As stated by most of the text-books, they are prone to disturb the stomach. That is true, but the chief objection is that these children do not expectorate; therefore, remedies which are supposed to assist expectoration are really of no use. If the remedy is one that will keep up nutrition or act as a cardiac stimulant, its use may be beneficial, but the ordinary expectorant, such as would be suitable for an adult or a child along in its teens, is contraindicated.

I believe the remedies upon which we must depend in this condition, are apomorphia, strychnia and alcohol in some form, either brandy or good whiskey, mixed with water. Apomorphia, although it has never, for some reason, crept into many of the text-books, is a most excellent remedy, for the reason that, in small doses frequently repeated, it tends to exert a systemic influence, thinning the secretion and thus keeping the weakened air-cells from sticking together. By thinning the secretion it enables the blood to take it up. These children do not expectorate; if they do get up any of the secretion they swallow it; therefore, it must be taken care of by the general blood stream, and to assist this the use of apomorphia should be begun early, as soon as we are sure of the diagnosis, as evidenced by a rise in temperature, rapid respiration; the child is sleepy and drowsy and ready to go to bed, and pays no attention to its playthings.

Strychnia is a good respiratory stimulant and, in addition, improves the nervous and cardiovascular tone to a certain extent. Alcohol stimulation, I believe, is a good thing. It not only keeps up the nutrition, but also tends to help the blood vessels along. Its use should be begun early.

In the later stage of the disease it is simply a question of fighting it symptomatically. Sometimes the patient will be benefited by minute doses of adrenalin, intravenously, when the case is apparently slipping beyond control. Digitalin (Hoffman-Laitche) is the best form of digitalis, in my opinion.

An interesting feature of the case reported by Dr. Read is the hemorrhage which occurred. I have never seen anything like the amount of hemorrhage he mentioned. I have once or twice seen a little hemorrhage from what I took to be a congested condition of the stomach in conjunction with the harassing character of the cough, but I have never seen a rupture of a large vessel.

The general management of the case as outlined by Dr. Read is about all that could be desired. In these cases we must depend upon Nature rather than upon the specific effect of any of the medicinal agents that we have at our command.

A Voice: Do you believe that the enlargement of the liver in the case reported could have had

any connection with the haematemesis, possibly by damming back the blood in the gastric veins?

W. A. Jenkins: I have just stated that I believe the hemorrhage to have been due to a passive congestion. It could not have been otherwise. It is not probable that an ulcer, as we understand ulcer in an adult, could have been present. In my opinion it must have been due to passive congestion resulting in rupture of one of the smaller vessels.

So far as the liver is concerned, in any infant or young child the liver occupies almost two-thirds of the abdomen, and in older children the large size of the liver in proportion to the other organs persists for many years. The liver does not get down to the important work that it performs in adult life for a long time. Many times, especially in rachitic children, the liver remains enlarged and the portal circulation is dammed back considerably. Generally, the rachitic condition and malnutrition produce practically as much of the stomach disturbance as the enlargement of the liver does.

Gaylord C. Hall: I will not presume to discuss this case from the standpoint of bronchial pneumonia, but I wish to say a few words in regard to the hemorrhage. I have seen a number of cases in infants where there was considerable hemorrhage from the naso-pharynx, explained presumably by the presence of engorged adenoid tissue which had undergone necrosis. I saw a case recently at the Children's Hospital, in which considerable quantities of blood were vomited as the result of a tonsillar condition, which the doctor spoke of as being present in his case. The hemorrhage did not come from the tonsil, but from congestion and subsequent rupture of the large vessels in the naso-pharynx, and I would suggest this as a possible cause of the hemorrhage in the case reported by Dr. Read.

W. Ed Grant: Dr. Jenkins suggested that alcohol is a useful remedy in these cases. I have always been in the habit of giving alcohol in these cases, feeling that it was useful in supporting the heart and as a general stimulant, but, in view of the fact, which has been demonstrated, that it tends to lower the germicidal power of the white blood cells, upon which we must depend to remove the cause of these infectious diseases, I question whether we should continue its use. Strychnia will support the heart, and does not interfere with the germicidal power of the blood. I am beginning to doubt the wisdom of giving alcohol in these cases because of its effect upon bacteriocidal properties of the blood.

C. G. Forsee: I think one means at our command which is sadly neglected, and especially in the treatment of broncho-pneumonia, is oxygen. When the patient begins to get blue around the finger-nails, there is nothing from which you can obtain such quick results as from oxygen. It acts just as well in broncho-pneumonia as in patients who have over-anesthetized. In my opinion,

oxygen, some form of morphine and alcohol are essentials in the treatment.

H. L. Read, (Closing): In regard to the hemorrhage, I will say that I was sitting by the bedside when this patient raised up and vomited the blood, and the first movement from his bowels was just as dark and bloody as it could be.

As to the use of alcohol, I carried this patient along first on strychnin and digitalin, and, later, on brandy.

A CASE OF LUPUS VULGARIS.

By M. L. Ravitch, Louisville.

Mrs. L. L., age 52; met with an accident last August, falling forward on her nose, bruising it. Oedema developed. The inflammation did not subside but crept on until the whole nose was involved. The color became a dull red. Very soon, papules, nodules and flat infiltrations developed. No doubt there must have been a staphylococcal infection which caused the destruction of the tissue, before the lupoid nodules made their appearance.

When the case came under my observation two weeks ago, I noticed several papules which were softer than the surrounding skin. Their soft consistency and brownish red color have caused Hutcheson to liken it to "apple jelly." Central involution and ulceration of patches have occurred, leaving scarred areas. Diascopic examination showed lupus nodules.

In this case, exuberant ulceration sprang up and tissue hypertrophied. There has developed a papillomatous outgrowth which is a sign that inoculation from without was the mode of infection.

As the patient brought suit against the city, I unknowingly and unwillingly became a witness for the plaintiff. I don't care what the outcome of the law suit may be, I will only try to treat the patient to the best of my knowledge and testify to what I have found. A tuberculin test (Moro's) was made and the patient reacted to it. My prognosis in this case is not a favorable one as the mixed infection is too extensive.

DISCUSSION.

Dunning S. Wilson: My experience in this class of cases has possibly not been as large as that of Dr. Ravitch; but, while I will not say that X-ray treatment of this condition is entirely worthless, it is undoubtedly much more painful than treatment with tuberculin, both subcutaneously and applied to the site of the lesion, as has been advocated by so many men. I recall one case that came under my observation with a tuberculous skin lesion that extended all over the shoulder. This woman had suffered intense agony under X-ray treatment with practically no results, and yet under tuberculin treatment

she showed remarkable improvement. While in this case sufficient time has not elapsed to permit of a positive statement as to the ultimate outcome, I certainly feel that we have by no means exhausted our resources in these cases until tuberculin treatment has been given a thorough trial. X-ray treatment is very painful, and I have seen no positive results from it.

J. Hunter Peak: Many years ago the late Dr. Holloway had a case which he was fond of exhibiting in his clinics as a case of typical tuberculous lesions of the hand and arm. Later, some 10 or 12 years ago I was called to treat that woman for erysipelas in that hand and arm. I think it was one of the worst cases of erysipelas I ever saw for the patient to get well. It extended over the whole arm and most of the right side of the body, and when that woman finally recovered from the erysipelas condition, the tuberculous lesions had disappeared and she has remained well ever since.

M. L. Ravitch, (Closing): In regard to tuberculin treatment, that is all right if the condition is due to joint tuberculosis. This patient gave a history of having enjoyed good health up to the time she was injured. Many of the most prominent skin specialists in the country have used tuberculin in the treatment of this condition during the past five years, but none of them, so far as I know, have reported my marked degree of success with it. On the other hand, many cases have been reported in which splendid results have been obtained from X-ray treatment. Dr. Wilson says that the X-rays are very painful. That has not been my experience, and I have obtained some excellent results in the treatment of skin lesions by means of the X-rays.

Laparotomy for Placenta Previa.—In the first two of the three cases reported the patients were elderly primiparae and after considerable hemorrhage the child was removed by Cesarean section and both mother and children were dismissed in good condition, with nothing to interfere with future pregnancies. The third patient was a woman of 40 at term with her eighth pregnancy, faint from excessive losses of blood, the fetus dead. The abdomen was opened and the uterine arteries ligated and ligaments tied off. The pulse began to improve at once, and supravaginal amputation of the unopened uterus was rapidly done and the patient was replaced in a warm bed, the pelvis raised.

Myomas and the Circulation.—Patta and Decio injected dogs with extracts from nine myomas and also extract of uterus tissue. The myoma extract seemed to have a pronounced action on the circulation in some respects, inducing bradycardia, palpitation and asthma in the animals, but no influence on the blood-pressure could be detected unless possibly a depressing influence.

MEDICAL PROGRESS

DEPARTMENT OF ORTHOPEDIC SURGERY.

Edited by WILLIAM O. HUMPHREY, Louisville.

1. THE TREATMENT OF TUBERCULOUS JOINT DISEASE WITH CARL SPENGLER'S "I K" SERUM.—*Amer. Jour. Orthopedic Surgery*, Feb. 1912.—The author's report (preliminary) Seven cases treated with I K (Immune Körper) serum and believe it has some curative properties. All their cases show positive and immediate constitutional improvement, with a marked diminution, after a few doses, of the discharge from sinuses, and a magic-like disappearance of pain after first dose. Two patients had bradycardia, during treatment and one had severe lytic distress.

Small doses at intervals of seven or eight days proved more satisfactory than the more frequent dosage. Disturbance of patient's comfort, guide for reduction of dosage. The posterior, extensor aspect of forearm, the least painful site for injection.

Tincture of digitalis or strophanthus should be administered throughout treatment. Jumping to ten fold dosage is both dangerous and unnecessary. Treatment should be carried over a period of six to nine months. Tuberculous patients with severe or advanced organic heart lesions should not be treated with I. K. until entire compensation has been restored, and then only while in bed.

II. CONSERVATIVE TREATMENT OF HIP-JOINT DISEASE.—*Amer. Jour. Orthopedic Surgery*, Feb. 1912.—Treatment should include improved hygiene in the broadest sense, residence at the sea shore, forced feeding as described by Dr. S. Solis Cohen, of Philadelphia and which consist of the use of rich and nutritious food in great abundance, sunlight and fresh air and the use of a new splint which is most beneficial and curative in the treatment of this condition. The exclusive use of milk and eggs is not commended. The splint as described by Young consists of a perforated hard leather body portion, extending from axilla to the lower third of the thigh on affected side, a perforated hard leather portion over the calf, and another perforated hard leather portion fitted to the foot, these parts being connected together by a sliding bar fixed with two screws and each portion reinforced by steel bands. The brace is put on with the patient lying down, first lacing the body portion and fastening the perineal straps, next pulling the foot down in the shoe, after which the thigh and calf portions are adjusted. A cork patton 2 1-2 inches high is worn on the sound foot and crutches are used. This brace affords besides the two universal-

ly recognized principles in the treatment of hip-joint disease—traction and fixation, fixation of the foot latterly to which the author attributes the enhanced value of the new splint.

III. AN OPERATION FOR CLAWED TOES.—*Amer. Jour. Orthopedic Surgery*, Feb. 1912.—The operation as done by Phil Hoffman since March, 1908, is excision of the heads and if necessary of parts of the necks of the metatarsal bones of all the affected toes, through a single transverse curved plantar incision just behind the web of the toes. After turning the flap down, the flexor tendons are carefully pulled aside exposing the metatarsal heads. The bones are divided with either a straight bone forceps or a narrow chisel, and a sufficient amount removed to relax all contracted tissues and to permit free motion between the phalangeal bases and the resulting metatarsal stumps without crowding one against the other.

The wound is closed with catgut and a simple aseptic dressing applied without a splint. Tenotomy of contracted tendons is unnecessary. The author has found the affection rather a common one, and his end results favorable, affording freely movable and serviceable joints in feet that are painless, and functionally, surprisingly good.

IV. BASIC CAUSE OF FLATFOOT.—*Medical Record*, May 11, 1912.—Having failed to find a logical reason in the Text Books why flatfoot should be so prevalent Mitchell contends that the basic cause of flatfoot is a slow absorption of calcium salts from the bones of the foot. Gravity directs a relatively larger amount of blood with greater force to the foot than to any other part of the body. This would subject the foot to increased absorption of salts. Further, the muscles of the leg, with intermittent activity, impel a vigorous current, which in turn induces an active circulation of the blood, the more active its powers of absorption. As all absorption varies directly as the motion, so all calcium absorption must vary directly as the motion, and Mitchell advances the theory that a rigid gastrocnemius is nature's attempt to limit calcium absorption. If the basic cause of flatfoot be lime absorption, then its consideration teaches that a cure in the late stage is impossible. A simple means of prevention is advised. Such a method would require a diet rich in lime salts, as contained in milk, eggs, fruits and vegetables; the avoidance of decalcifying acid food, and the drinking of water known to contain the physiologic minerals.

V. INDICATIONS FOR SURGICAL INTERFERENCE IN TUBERCULOUS JOINT DISEASE IN CHILDREN.—A. H. Tubby (*Lancet*, Jan. 6, 1912, says the balance of experience gained in the

treatment during the last decade shows that unquestionably conservative treatment is better in childhood. Time is saved, the resultant deformity is diminished, and there is less risk of generalized tuberculosis when treatment is non-operative. When abscess is present its sack should neither be allowed to become adherent to the skin, nor to open spontaneously, as an opening often forms in an undesirable position and is liable to septic infection. When pus continually reforms it is generally due to extension of bone disease or to loose sequestra, which can be ascertained by means of Roentgen rays.

It is doubtful whether operative results are better in cases of tuberculosis of the hip-joint, than those obtained by rest and splints. The safest course in tuberculosis of the knee-joint is to give a long and patient trial to conservative treatment, and, if this fails, to give up all hopes of a movable joint and do a formal excision, having regard to the epiphyseal lines, and endeavor to secure sound bony ankylosis and a straight limb.

Even in dealing with the ankle and foot, statistics show the best results to be obtained by rest and conservative treatment. Erasion frequently proves to be better than a formal excision when conservative treatment fails.

VI. TREATMENT OF RESIDUAL PARALYSIS OF ANTERIOR POLIOMYELITIS.—B. Bartow and W. W. Blummer, *Bull. Med. Jour.*, 1912, LXVII, 310. The writers favor the replacement of weak ligaments with artificial ligaments of silk and described the method of inserting the artificial ligament. The silk used for the artificial ligament was the parafined silk tendon prepared in the manner suggested by Lange for tendon elongation. Number 20 Corticelli twisted silk was the size used in the earlier operations for both knee and ankle. Roughly estimated, after the operation, the tensile strength of the artificial ligament is sufficient to sustain a direct strain of 125 pounds. For the fixation of the feet in very young children, number 14 size is used with satisfactory results, and greater ease of introduction. No tendency has thus far been shown for the silk ligaments to cut their way out of the joint, or cause sloughing of the tissues in contact with them. They become looser, however, with time and use of the limb.

As they cannot stretch the chief source of looseness is probably from absorption of the bone in which they are buried at points where tension is greatest.

Identity of Brill's Disease with Typhus.—Cheimisse presents and reviews the date that have accumulated on this subject, endorsing the identity of these two diseases in accordance with the editorial in *The Journal A. M. A.*, Feb. 10, 1912, p. 414.

JEFFERSON COUNTY MEDICAL MILK COMMISSION NEWS.

The Medical Milk Commission of the Jefferson County Medical Society has asked for and has been granted the privilege by the Editorial Committee of the *Jefferson County number of the KENTUCKY MEDICAL JOURNAL* of contributing once a month some report of their work, so as to keep the profession in touch with their activities and to obtain their assistance in spreading the gospel of clean milk.

The last annual meeting of the American Association of Medical Milk Commissioners held in Louisville at the Seelbach Hotel adopted a manual of working methods and standards which sets the goal toward which all commissions are striving. We wish to assure the profession that the Jefferson County Medical Milk Commission is trying at all times to keep the milk, certified to by it, up to the high standard set by the American Association. In this connection it might be of interest to know that at the recent meeting in Louisville the representative of the Bureau of Animal Industry of the Federal Government, announced that one of the dairymen, certified to by our commission, received the first prize for the best milk and cream entered at the recent milk show in Chicago. He stated that these were the best samples of milk and cream which had ever been submitted in a milk contest.

It is the desire of the Jefferson County Commission to assist the profession generally to elevate the standard of market milk and to that end suggests that all County Medical Societies appoint Milk Committees with the primary purpose of elevating the standard of the general milk supply in their community which will finally lead to the creation of Milk Commissions which can begin certification of milk when the community has been educated to the importance of having this supply and the dairymen to the point of producing it. It is the hope of the local commission that finally enough medical milk commissions will be formed in the State to warrant the organization of a State Association of Medical Milk Commissions, such as exists in the state of California. By such an organization the distribution of clean milk propaganda will be facilitated and mutual assistance can be had in the enforcement of the rules and regulations laid down in the manual of working methods and standards by the American Association.

The commission annually enforces the tuberculin test of all cows in certified herds and this work will shortly be done under the supervision of the Commission.

CAUSES AND TREATMENT OF CONVULSIONS IN INFANCY AND CHILDHOOD.*

By E. L. GOWDY, Campbellsville.

It is with hesitation that I bring before you a subject so familiar, and the limits of discussion of which are so narrow, as that of convulsions in infancy and childhood, because probably in no other condition is there a symptom of a disease where a routine treatment is more universally and successfully employed. While the progress in scientific infant feeding, in serum therapy, and the treatment of diseases of childhood in general have made most wonderful strides in the last few years, the text-books of twenty years ago contain essentially the same line of treatment in convulsions that is advised by the text-books of to-day. The best reason for this is that, in most cases, the means recommended are successful—they stop the spasms; and every doctor, especially the young doctor, knows there is no way that he can more quickly earn the sincere gratitude and friendship of a family and feel so thoroughly satisfied with himself than to speedily and successfully relieve an infant with convulsions.

While numbing the child's brain with morphine and poisoning its blood with chloroform will usually terminate, or rather hold in check an attack, I am convinced that these means lead many doctors to a feeling of false security, and they fail to fully investigate the problem that presents itself to them. There is no condition met that requires profounder thought or more careful study than the cause of convulsions in children: for, while one convulsion rarely terminates fatally, even seriously, the failure to fully appreciate the cause may lead to subsequent spasms that will leave the little sufferer a helpless paralytic or an idiot.

There are almost as many classifications of convulsions as there are writers on the subject, but as this paper is intended primarily as a discussion of convulsions in general, I shall consider: (1) Predisposing causes and (2) Exciting and reflex causes. It does not come within the scope of this paper to discuss those convulsions that are brought about by intrauterine affections, injuries at birth, and causes that operate soon after birth. These convulsions, which are properly classified as eclampsia neonatorum, usually come within the first three months of life and deserve separate consideration.

Although rickets is less common in the country than in cities, there is no doubt but that it is the most prominent predisposing fac-

tor in the production of convulsions. One writer has stated that 40 per cent. to 50 per cent. of children subject to convulsions are rachitic, but this estimate is rather high. Rickets, is a disturbance of metabolism, and the sensitive nervous system that accompanies these nutritional diseases makes the child susceptible to the great number of reflex causes, including worms, burns, wounds, dentition, adenoids and middle ear disease that play a part in the cause of convulsions. Often a case of hitherto unsuspected rickets can be diagnosed by a close investigation of one of the more direct or exciting factors of an attack.

Some authorities have observed that a disturbance of secretion of some of the ductless glands, especially the thymus, is prominent as a cause of convulsions, but as there is usually more or less of a disturbance of secretion of these glands in rachitic children, it is, after all, probable that rickets, in the majority of instances, is the leading predisposing cause in convulsions attributed to this condition.

It is in the treatment of convulsions due to rickets that the physician is put to the severest test. As one attack predisposes to another, unless satisfactory treatment is instituted, we are likely to have an epileptic or a weakling before the child is many months old, but, unfortunately, there is no immediately satisfactory treatment of rickets. The "old reliable" phosphorus-cod-liver oil treatment has proven to be a myth. It has been shown that, as a rule, it is not a lack of calcium salts in the food that produces rickets, but an inability to properly assimilate those which are supplied. It is impossible to produce a case of true rachitis by withdrawing calcium from the food.

While the pathological changes in rickets are well understood, the cause of this disease, so harmless in itself, yet often so disastrous in its results, is not even known. Hanseman considered it resulted from too little air and exercise, as children born in the fall and living in bad quarters are more likely to develop rickets than those born in the spring and living in similar surroundings. Sittler believes it a disturbance of digestion caused by unhygienic surroundings. Czerny defines rickets as a true constitutional anomaly. Elbettez observed that rickets is a comparatively rare disease in the tropics, and increased, irrespective of race, the greater the distance from the equator, hence he concludes rickets is caused by lack of light. J. Koch and Kassowitz believe that rickets is caused by changes in the parts due to bacterial infection. In America, it is a rule to consider rickets as a result of unsuitable food. This is especially true when children develop rickets after a prolonged diet of condensed milk. But as condensed milk is usually the last resort in artificially fed

*Read before the Muldraugh Hill Medical Society.

babies—the food the doctor recommends when all else fails—we have a weakened subject to begin with who might develop rickets even on the most approved diet. Although the formula of condensed milk seems theoretically impossible, I believe it bears more than its share of blame in the production of rickets.

I have dwelt at some length on rickets as a predisposing cause, because, as I have before intimated, it is this class of cases that is likely to give us the most trouble, and every effort should be made to improve the rachitic condition. From a study of these latest theories as to the cause of the disease, it seems that the best treatment is hygienic, as little dependence can be put in drugs to bring about a removal of the condition.

The other great predisposing cause of convulsions, and one over which the doctor, as a rule, has little or no control, is nervous heredity. These children are usually born of syphilitics, alcoholic, hysterical, gouty or consumptive parents. There is no law that prevents these people from marrying. There is no law, and never will be, that separates a child from an actively tubercular parent. It is true that because of the extra care a tubercular parent sometimes gives his children, they are less likely to contract consumption, but, unfortunately the vast majority of consumptives do not realize the need of care till it is too late. And even the ordinarily careful sometimes grow careless, for consumption is indeed a disease where "death takes on the glow and hue of life" they think they are always getting better, and children continue to inherit weak resisting powers and die of tuberculosis.

A syphilitic or alcoholic inheritance is even worse than a tubercular one; for in these conditions the weakened nervous state is manifest from birth, and, if convulsions set in, the prognosis is always grave. Under this head may be mentioned the observation that children who have one parent young and the other old, especially if the father is old, show less resisting powers than children the ages of whose parents are more nearly equal.

On the other hand, there are children born of perfectly healthy parents who may acquire a nervous state that is just as strong a predisposing cause of convulsions as a neurotic inheritance. Of course, the pregnant woman, for obvious reasons, should be preserved from undue excitement or shock, but so long as she eats plenty, has plenty of fresh air, sleeps well and knows how to take any sort of systematic care of herself, great anxiety or sorrow are not likely to have any special effect on the nervous system of the child. It is after birth that the overzealous mother or nurse is likely to pave the way to more or less direful results. It does not take the spoiled baby

long to become a "bundle of nerves," the mother becomes frantic when the child is seized with a convulsion because of some slight irritant, and never realizes that she is as much to blame for the attack as anything else.

There is another class of mothers, less indulgent, but whose methods of raising the child are just as disastrous. I refer to those mothers who have a fixed schedule by which they raise their babies. Nearly all babies brought up according to a strict formula are nervous. The good effect of proper clothing and proper room temperature is more than overcome by the interrupted sleep and interrupted play these babies have to endure.

In discussing the exciting causes, I shall first consider those that come during the pre-dentition period. Excluding gross brain lesions and organic lesions of the heart, liver and stomach, the most common cause of pre-dentition convulsions is dietetic errors. In the majority of instances these are brought about by disturbance of lactation in the mother; but, shameful to say, we still have that class of the ignorant and unenlightened who persist in the disgusting and murderous practice of chewing food and placing it in the baby's mouth. The selfish mother or nurse gets the nutrition out of the meat, and the baby gets the tough indigestible fiber, and syphilis, tuberclosis, and convulsions. Of course, the various reflex causes, such as eye disorders, anemia, genital defects, nephritis, and the onset of acute diseases may play a part in the production of convulsions during this period, but the vast majority may be traced to some error in feeding.

The exanthemata are rarely ushered in by convulsions, and a most careful examination should be made before ascribing a convulsion to the onset of an acute disease. In cases of doubt, it is well to take the rectal temperature in convulsions that happen during any period of a child's life. Those denoting infectious diseases will usually show a high temperature, although the skin may be cool; those accompanying rickets, tetany and epilepsy are non-febrile or only slightly so.

Convulsions appearing between the period of primary and secondary dentition constitute the vast majority that come under the observation of the doctor. It is during the period of primary dentition that the so-called "teething convulsions" with their accompanying gastro-intestinal symptoms take place. The point to be borne in mind, however, is the fact that more often it is the intestinal involvement that is not only the cause of the convulsion, but of the condition of the gums as well. The practice of gum lancing is to be mentioned almost to be condemned. While there are occasional instances where lancing may give great relief, the ma-

majority of tender, inflamed and swollen gums will yield very readily to a brisk calomel purge and absolute cleanliness about the mouth, a most excellent wash for this purpose being glycerine and water, to which chlorate of potash, about ten grain to the ounce, is added.

Normal teething is a practically painless process, and a child with a teething convulsion is likely to have another unless some error in diet is corrected and the stomach and bowels kept in good order. It should be remembered that earache in children will often bring about the same feverish, fretful symptoms, including spasms, that are attributed to teething, and in cases of doubtful etiology the ear should be examined as a possible source of the trouble.

Gastro-intestinal intoxication is undoubtedly the cause of the greatest number of convulsions, and, in my opinion, the intoxication that brings about a convulsion is usually bacterial in origin. The child suffering with an ordinary food intoxication with its dull, heavy, half-closed and drowsy eyes presents an entirely different picture from the pale, anxious, restless expression of a baby before it enters into a convulsion. Of course, simple food intoxication may become so deep that the poison will soadden the more or less undeveloped controlling centers of the baby's brain that they lose all power over the higher cortical centers and convulsions will follow. But, as a general thing, in patients presenting the dull, listless symptoms of simple food intoxication, the beginning of summer complaint, if convulsions develop at all, they are likely to come during a later stage of the disease.

TREATMENT.

While the treatment, usually prophylactic, has already been outlined under certain headings in this paper, the question remains: What is the best procedure when we are called to treat an attack? I know of no special objection to the mustard bath; but the best results obtained from its use is that it gives the excited parent something to do till the doctor arrives. Usually the disturbance of the infant in getting it disrobed, placed in the bath, and afterwards sponged and dried overcomes any beneficial effect the bath might have.

When the doctor arrives the little patient is usually comatose or has that weak, fretful cry, the precursor of another convulsion. If possible, the child should immediately be given a dose of castor oil, and the bowel washed out with salt solution. While we are preparing for this procedure, if we can assure ourselves that the convulsion is not due to the onset of an acute disease, an injection of bromide of soda and chloral should be left in the bowel.

Emetics, especially mustard, should never be used; the stomach tube is the only justifiable resource if the stomach has to be emptied.

If these means fail to arrest the spasms, our safest and surest remedy is the hypodermic administration of morphine. I am unable to see the advantage of the use of chloroform inhalations in these conditions; at best, they can only bring about a temporary cessation of the spasm, or rather cut short an attack already on, and I am not convinced that the use of chloroform is without danger. It relieves the attack at the expense of the respiratory tract and blood, and lessens that supply of oxygen that is so grateful to a patient in this condition. In my opinion, the only indication for its use is in a quick succession of convulsions, when it may be used till the morphine has had time to take effect.

The dose should not be too small, for children with convulsions bear it unusually well. 1-30 to 1-20 of a grain may be given to a child six months old, but this dose should not be repeated within twelve hours. Hydrobromide of hyosine is a favorite with English physicians, but I have never seen it used.

If these means fail, the next resort is blood-letting. The withdrawing of blood from an infant is a heroic measure, but it is often the means of saving life. Two or three ounces of normal saline should be injected into the soft tissues of the child, and one-half to one and one-half ounces of blood withdrawn, according to the age and condition of the patient.

Oxygen by inhalation is of unquestioned value, but its use at present is not practical to the average general practitioner.

The after treatment of an attack is to pay strict attention to diet and to keep the child quiet. For the first forty-eight hours, it is best, in most cases, to keep the child under the influence of a mild sedative, bromide of soda combined with calomel for the first twelve to twenty-four hours and adrenalin for the next day or two being excellent for this purpose. Any reflex source of irritation should, of course, be corrected as soon as the child's general condition will permit.

Formation of Artificial Vagina by Intestinal Implantation.

—De Bovis discusses the various methods of forming a vagina out of a loop of intestine, stating that it has been done in eleven cases and that the functional outcome was satisfactory in all. Dreyfus has recently reported utilizing a hernial sac for the purpose, and Ott and Stoeckel made a vagina out of peritoneum, but the operation was not a success in either instance. (Stoeckel's success with a loop of intestine was recently described in *The Journal A. M. A.*, Feb. 10, 1912, p. 451.)

THE NEW DRINKING CUP LAW.

Mainly through the influence of the State Federation of Women's Clubs, and under the splendid leadership of Hon. W. E. Dowling, Senator from the Anderson-Franklin-Mercer district, the last General Assembly passed the following bill and it was promptly approved by the Governor and is now effective all over the State:

AN ACT PROHIBITING THE USE OF PUBLIC DRINKING CUPS.

Be it enacted by the General Assembly of the Commonwealth of Kentucky:

The use of the common drinking cup on railroad trains, and in railroad stations, public hotels, boarding houses, restaurants, or steamboats, in stores or other frequented places in Kentucky, is hereby prohibited. No person or corporation in charge of the aforesaid places, and no person or corporation shall permit on said railroad train, in railroad stations, public hotels, boarding houses, restaurants, steamboats, stores, or any publicly frequented place in Kentucky, the use of the drinking cup in common. There must also be posted in a conspicuous place, by the drinking water contained in any of the places mentioned in foregoing paragraph, a warning card-board, with the above printed thereon in large letters, so they can be easily read. Any person or corporation violating the provision of this act shall, upon conviction, be fined in any sum not less than one dollar, and not more than ten dollars, and each day's violation of any of the provisions of this act shall be considered a separate offense, punishable by fine in the amount named above.

All laws inconsistent with this act are hereby repealed.

Practically the same law is in operation in many other States and its proper enforcement will have great influence in the prevention of many of the common communicable diseases, and especially in the prevention of syphilis. The profession knows the importance of this precautionary measure as most other people cannot, and it should be enforced for all court houses, livery stables, stores, mines and other semi-public places equally with those named in the statute.

DR. RODMAN.

The only matter of regret in connection with the above name is that there are not more of them. The following clipping from Bardstown tells about the seventieth birthday of one of the youngest and most active members of the family. Dr. Hugh Rodman's whole life has been a credit to his profession, to Kentucky, and to himself. No man has contributed more towards producing ideal conditions amongst the practitioners of his own county:

"On Wednesday, May 22, Dr. Hugh Rodman, of Bardstown, gave a delightful six o'clock birthday dinner to all the other physicians in town.

"On this day Dr. Rodman had reached the venerable age of three score and ten years.

"It has been some time since the Doctor began the laborious journey of life, and his pathway, like all others, no doubt, has led him over more rocks and crags than upon grassy lawns and flowery fields, but he has passed along the rugged road with an unfaltering nerve, strength, bravery and dexterity.

"Life is a grand mission. We are placed here to make the world better, to lift it up

to higher levels of enjoyment and progress to make the hearts and homes brighter and happier, by devoting to our fellowmen our best thoughts, influences and activities, and in this respect the Doctor has fulfilled the Master's will to the best of his ability.

"Early in life Dr. Rodman chose a high, noble calling as his profession, and by necessity being brought into such close touch with sickness, pain and sorrow, the splendid qualities of kindness, sympathy and charity were fully developed in his nature.

"Dr. Rodman is at present President of the Board of Health of Nelson County. He has always been a successful physician, having read, studied and attended all associations relating to his profession, thereby keeping abreast of the times.

"If it is a law of our intellectual and moral enjoyment to promote our own happiness in proportion as we promote the happiness of others, then we know the Doctor has enjoyed a good deal of happiness in his life, and the friends of the good Doctor are better too, for having him pass our way and we heartily wish that his life will be prolonged for many years to come and that he will have the happiness of being the host at many more pleasant birthday dinners.

"The Scripture saith three score and ten
Is a good old age for the most of men;
But once in a while, by reason of strength,
The days of a man reach greater length.

"And the Scripture saith where two or three,
Concerning aught that's good, agree—
And send a fervent prayer to heaven
A certain answer will be given.

"So, brother, at your festal board
With appetizing dainties stored,
While we partake of toothsome dishes,
We offer you our heartfelt wishes—

"That, in the coming years, Time's sands
May run as smoothly, and Time's hands
Be laid as gently on your head,
As in the years already sped!

"May happiness and vigor last
Until, the eightieth mile-stone passed,
You enter on another score;
And even then—

May
Heaven
Send
More!"

FAYETTE COUNTY.

The Fayette County Medical Society is receiving congratulations upon a membership of 66 with two applications pending. This is the largest membership in the history of Fayette County and is a direct return for the splendid work both along the general lines of scientific medicine and, also, as regards the medical society as the guardian of public health. The Fayette County Medical Society is one of the very strongest in Kentucky and the recent articles contributed to this JOURNAL by its membership shows that its very effective secretary, Dr. L. C. Redmon, is the right man in the right place.

THE WHITE MAN IN THE TROPICS.

During the past four years there has taken place in the medical Journals of this country more or less of a discussion concerning the action of tropical sunlight upon the white man. The general consensus of opinion has been adverse. In a recent article in the *Popular Science Monthly* (June), Dr. Paul T. Freer, whose untimely death occurred a short time ago, contributes an article of considerable interest, under the title of "Tropical Sunlight." This article is written in a scientific and temperate manner, free from anything like partisanship, and endeavors to consider the whole question therein involved. We read: "The races of people native to the tropical zones have no knowledge of bacteriology and pathology, which would enable them to understand the measures to be taken to avoid infections and other diseases, whereas they live in regions where the absence of a pronounced winter is favorable to the rich development of microscopical life. As a consequence, many of the ill effects which are attributed to sunlight, may, in reality be due to entirely different causes. * * * Another factor influencing local conditions may be the color of the soil, and the resulting modification of the intensity of the heat rays coming from it, because the radiation from the soil is of importance. * * * Prevailing winds may so modify the climate of the region that during the night the temperature may correspond to those found in places more favorably placed. * * * The general trend of discussion in the literature has been that the rays of the sun, lying in the region of the spectrum, comprising the violet and ultra-violet are of the greatest importance in determining the influence of insolation upon the human beings and these rays have a special, though undeserved, designation as actinic rays."

Many experiments were performed, the most interesting being those pertaining to monkeys and human beings. We quote,

"Monkeys are naturally at home in the tropics and we should suppose that they would best be able to withstand the effect of sunlight. They have a system of sweat glands, but this is not so highly organized as it is in man, so that their physical heat regulation is brought about not only by evaporation of sweat, but also to a very great extent by water evaporated from the lungs and mouth through increased respiration." He found that exposure to sunlight rapidly killed the monkeys but that even the slightest shade by an umbrella or a small piece of board would produce entirely different results. If the monkey was exposed to the direct sunlight but the excessive heat conducted away by a brisk current of air from a fan, the same results were obtained as if the monkey was shaded. Thus, it would seem that the untoward effects were due not to the ultraviolet, but to the heat rays.

"Experiments on man have shown that the ultraviolet rays are easily guarded against by shade or even by a white cotton shirt; the heat rays not." Investigating the White, Malay and Negro races, the "comparison showed but little difference between the white and the Malay, the difference, if any being in favor of the latter, but a negro, in a series of observations, exposed to the sun at the same time as a blond European and a brown Igorot, showed a higher skin temperature by 1.45 degrees than the Caucasian. At the end of the experiment the final temperatures were decidedly against the negro, slightly against the Tagalog, and in favor of the white skin. Therefore, so far as they have gone, our experiments seem to show, as regards rise in temperature upon exposure to the sun, that the white and brown skins are about equal, with a slight factor in favor of the white, but that in the case of the very dark-skinned negro the temperature, on exposure, reaches a decidedly higher point than it does with either of the others. The dark skin of the negro obviously will absorb heat more readily than the lighter one of the European, and also will radiate more readily, the heat taken up on the sunny side being rapidly lost on the shady one; but this balance evidently results in a greater rise of temperature for the negro than for the white man." In a number of experiments made with white, gray and black rabbits, the conclusion was reached that the darker the coat, the greater the heat absorption and the more apparent do the effects of insulation become. These experiments undoubtedly show what long practical experience had taught, that the whiter the clothing the better it is adapted for protection against sunlight and that even in the tropics, if care is taken to seek the shade, no untoward effects can be observed. Chamberlain found

also that even after three years' residence in the Philippines the blood pressure did not tend to increase or decrease.

Of the effects of ions in the air and the total ionization brought about by radioactivity, may have a considerable influence in controlling the electro and other meteorological phenomena, and work is now being conducted along these lines.

It would thus seem that the sensible solution of avoidance of injury to health in the tropics was not one of an avoidance of tropical sunlight, but that the maintenance of health within these regions really depend upon the intelligent and rational observation of hygienic laws, both as regards food and dress; the proper kind, character and color of the clothing and the strict avoidance of all alcoholic beverages, tainted and impure water, together with the strict elimination of such late and irregular hours as are conducive to general breakdown.

It would therefore seem that the advice to those entering the tropical regions would be about the same as that given to those who remain at home. After all the study of the result of experience, the addition of a good modicum of common sense and rational self-restraint will go far more toward the preservation of health in or out of the tropics than the mere avoidance of the much touted, and much dreaded, tropical sunshine.

SCIENTIFIC EDITORIALS.

SOMETHING ABOUT ADENOIDS.

At the meeting of the Otological Society of Denmark, December, 1911, Kiær cited some of the unusual conditions brought about by adenoid growths in children. He reported a case of recurrent epileptiform convulsions in a child of five years in which a cure (now four years) was brought about by removal of the adenoid growths. He further reports two cases of chorea which was cured by removal of adenoids.

Demetriades in a recent publication on the study of adenoids in Greece reports seven cases of epilepsy in 395 cases of adenoids all of which were cured by removal of adenoids. He also observed one case of chorea due to adenoids and cured by their removal.

Kiær pointed out the relation between adenoids and enuresis nocturna. Greenbech found that 14 per cent. of all children with adenoid were bed wetters, an observation corroborated by Myglin who found it in 23 per cent. of cases among the poor, but only 8 per cent. among the children brought up under better environments. Both of these authors report only 50 per cent. of cures of the enureses after the removal of the growths.

Instead, the morning following the experiment showed without exception a clear improvement over the work of the morning preceding the experiment.

As to the effect on muscular efficiency, *The Journal of the American Medical Association* says that the conclusion seems to be that caffeine enables the muscles to contract more vigorously without producing a secondary depression, so that the sum-total of muscular work which can be done by a man under caffeine is greater than that which can be done without it.

It is gratifying to have the effects of a drug like caffeine on the human system so investigated by rigorous scientific tests at the hands of capable investigators; only in this way will there be provided an adequate basis for correct conclusions as to the possible dangers of the use of caffeine-containing beverages.—(*Jour. A. M. A.*, March 16, 1912, p. 784).

REFORM IN MEDICINE.

NEWSPAPERS AND NOSTRUMS.—It appears to be impossible to so censor "patent-medicine" advertisements in newspapers so that all objectionable matter is rejected and only the unobjectionable retained. This for the reason that there is no such thing as an unobjectionable "patent-medicine" advertisement in a newspaper. In proof of this it is pointed out that the *Chicago Tribune*, whose advertising and editorial ethics are of a high order, carries many advertisements which promote remedies or treatments condemned in its editorial pages. Thus, while its "How to Keep Well" department warrants that it is not wise for the obese to reduce their weight more than ten or twenty pounds a year, an advertisement in the same issue for Majorie Hamilton's Obesity Cure claims that by its use fat may be made to vanish at the rate of one pound a day. A number of similar incongruities are discussed.—(*Jour. A. M. A.*, April 13, 1912, p. 1118.)

THORENEDIN SUBMITTED TO THE COUNCIL.

While acknowledging the correctness of the A. M. A. Chemical Laboratory analysis (*Jour. A. M. A.*, Mch. 9, 1912, p. 716), Squibb and Sons question the conclusions of Dr. Pusey that the product owes its virtues to sulphuric acid alone. The firm's claim that the product owes its virtues to the thorina which it contains was shown to the reports of physicians in whom it had confidence. The product has been submitted to the Council on Pharmacy and Chemistry and the firm agrees to discontinue the sale of Thorenedin if the Council confirms Dr. Pusey's findings.—(*Jour. A. M. A.*, April 13, 1912, p. 1121 and p. 1135).

"THERAPEUTIC EFFICIENCY."—The defenders of proprietary frauds of the so-called ethical variety make much of the fact that the rejection of a product by the Council on Pharmacy and Chemistry is no proof that the product itself has no therapeutic value. In reply it is pointed out that a mixture of quinin sulphate and starch while therapeutically efficient may yet be exploited so as to make the mixture a rank humbug or a vicious fraud.—(*Jour. A. M. A.*, April 13, 1912, p. 1121).

"PRESCRIPTION FAKES."—Oxzoil is a prescription fake advertised as a "wrinkle eradicator" and exploited by the To-Kalon Manufacturing Co., Syracuse, N. Y. According to the analysis of the state chemist of North Dakota it consists of zinc oxide 15.6 per cent., glycerin 16.7 per cent. and rose water 67.7 per cent. Saxolite is another "wrinkle eradicator" sold by the Dearborn Manufacturing Company, Chicago and according to the analysis of the state chemist of Kansas consists of alum 52 per cent. and epsom salts 48 per cent. Vilane Powder is sold as a "concentrated powerful antiseptic germicide and disinfectant" by the Blackburn Products Co., Dayton, Ohio. According to the analysis it is a mixture of washing soda, cooking soda, common salt, sodium salicylate and a little thymol.—(*Jour. A. M. A.*, April 13, 1912, p. 1132).

PROPHYLAXIS ENCOURAGED.—The Council on Pharmacy and Chemistry desires to encourage the use of reliable and efficient antiseptics, germicides and disinfectants by the public, so far as is compatible with safety. Accordingly it endorses the advertising to the public of such prescriptions accepted for inclusion with New and Nonofficial Remedies, provided that the advertising is limited to recommendations for use as a prophylactic application to superficial cuts and abrasions of the skin and to mucous surfaces except those of the eye and the gastro-intestinal and genito-urinary tracts.—(*Jour. A. M. A.*, April 13, 1912, p. 1132).

VALUE OF INORGANIC PHOSPHATE.—The wide-spread tendency to assume a better physiological utilization of certain inorganic elements when they are furnished in the form of organic combinations is gradually being shown to be without warrant. Thus while it was supposed that the body need of phosphorus could not be supplied by inorganic phosphates, hens and ducks have been shown to be capable of living and of laying eggs when their food contained phosphorus only in the inorganic form. This makes it probable that the advantage of giving phosphorus

in the form of lecithin or of glycerophosphates has been over-estimated.—(*Jour. A. M. A.*, April 20, 1912, p. 1198).

CANDY IN PENNSYLVANIA.—Good work is being done in Pennsylvania in the improvement of food products. A report of Charles H. LaWall shows that out of over 250 samples of cheap confectionery only 4 samples contained substances prohibited by law. Many specimens were found to be in a filthy condition and Professor LaWall recommends that manufacturers be compelled to wrap candies in paraffin paper.—(*Jour. A. M. A.*, April 20, 1912, p. 1202).

SANATOGEN.—According to advertisements, chiefly in the lay press, Sanatogen is "The Re-Creator of Lost Health," "a rebuilding food" and "revitalizes the overworked nervous system" and has many other properties which should make it an "elixir of life." Examination in the A. M. A. Chemical Laboratory shows it to be casein with a little glycerophosphate and therefore not greatly superior to cottage cheese. The outrageous claims made for it are condemned by such men as Lowells F. Barker, Frank Billings, Richard C. Cabot, Otto Folin, Lindvitz Hektoen, J. H. Long, Graham Lusk and H. Gideon Wells.—(*Jour. A. M. A.*, April 20, 1912, p. 1216).

VALUE OF FERMENTED MILKS.—P. G. Heinemann discusses the dietetic and therapeutic value of fermented milks prepared from commercial ferments. He concludes that sour milks as a part or rather than an addition to the diet probably are of value. If fermented milks are used then other food should be reduced on the basis of one pound of beef for every quart of milk consumed. There is much reason in the contention of Metchnikoff that premature senility can be prevented by regular diet, decrease of meat and regular consumption of Bulgarian sour milk, but it must not be thought that sour milk is a panacea and that by its use intestinal putrefaction will be reduced unless moderation in diet is practiced. The choice of a suitable ferment being of prime importance attention is called to those found efficient by the Council on Pharmacy and Chemistry and included in New and Nonofficial Remedies.—(*Jour. A. M. A.*, April 27, 1912, p. 1252).

ECKMAN'S ALTERNATIVE.—According to the analysis of the A. M. A. Chemical Laboratory Eckman's Alternative is a solution containing about 4 per cent. of calcium chloride, 10 to 15 per cent. alcohol and a little powdered cloves. This mixture is sold at \$2.00 for 8 ounces under the cruelly false claim that it will save

the tuberculous. The harm done by nostrums such as this lies in the abandonment of proper treatment by the patient and placing his dependence on the nostrum. Hoping against hope that in the "consumption cure" nostrum the secret has at last been wrested from nature by which the White Plague may be vanquished, the ever-optimistic consumptive sacrifices money which should go into good food, sacrifices all too precious time and, finally, life itself, and the consumption cure faker waxes rich in the toll of blood exacted from his credulous victims.—(*Jour. A. M. A.*, April 27, 1912, p. 1298).

ANTIDIABETICUM-BAUER.—The methods of advertising Antidiabeticum-Bauer have been shown up by the Society for the Suppression of Quackery. A suit by the proprietors of Antidiabeticum against the editor of the *Gesundheitslehrer* resulted in the defeat of the proprietary concern.—(*Jour. A. M. A.*, April 27, 1912, p. 1298).

PHENACETIN, SULPHONAL AND TRIONAL.—It is a generally recognized principle that the name used by a patentee to designate a patented article becomes the common name of such article after the patent has expired. This principle, and also the principle that a generic title—or common name—cannot be legally continued as a trademark have been generally recognized and are thoroughly well established by decisions of the courts. Accordingly the Council on Pharmacy and Chemistry has modified the descriptions for these articles in New and Nonofficial Remedies to indicate more clearly that the names "phenacetin," "sulphonal" and "trional" are synonymous for the official titles acetophenetidin, sulphonmethane and sulphonyl methane, respectively, and that the tests of identity and purity prescribed in the U. S. Pharmacopoeia should apply to the products under these titles.—(*Jour. A. M. A.*, April 27, 1912, p. 1298).

THE SARSAPARILLA ABSURDITY.—Sarsaparilla is an almost universal constituent of "blood purifiers" (whatever that may mean). Preparations of it are also official in our Pharmacopoeia. The fact that the drug is almost never used alone, but is almost always combined with something more active such as potassium iodid, shows that no one places any dependence on it. The Pharmacopoeia should be purged of sarsaparilla and its preparations, if it is to continue to enjoy its own self-respect.—(*Jour. A. M. A.*, May 4, 1912, p. 1356).

THERAPEUTIC RESEARCH.—Torold Sollmann, Chairman of the Committee on Therapeutic

Research of the Council on Pharmacy and Chemistry, discusses the need of more exact knowledge regarding the action of drugs. He outlines the plans whereby the Council hopes to aid therapeutic research. The following are some of the problems now being investigated: The clinical value of cardiovascular drugs, relative efficiency and toleration of natural and synthetic salicylates, duration of action and absorption of digitalis bodies, efficiency of intestinal antiseptics, therapeutics of phosphorus compounds, standardization of antiseptics and germicides, pharmacology of commercial valium preparations, effects of origin and impurities on toxicity of chloroform, and fate, efficiency and side actions of organic iodids.—(*Jour. A. M. A.*, May 4, 1912, p. 1390).

ALCOLA.—This "cure for drunkenness," consisting of three kinds of tablets, was examined in the Association Chemical Laboratory. Tablets No. 1 contain caffeine, about 1-4 grain and strychnine, nearly 1-50 grain. Tablets No. 2 contain strychnine, about 1-100 grain. Tablets No. 3 contain tartar emetic about 1-2 grain. While this is a full dose of tartar emetic, the directions suggest that as many as 3 or 4 tablets may be taken without harm. Alcola is exploited by the Physicians Cooperative Association of Chicago, which also sells Re-Ves-To claimed to cure rheumatism, kidney diseases, liver and bladder trouble.—(*Jour. A. M. A.*, May 4, 1912, p. 1390).

RELIABLE MEDICINES.

Neisser Bacterin Mixed, a gonococcus vaccine, each Cc. being said to contain approximately 100 millions each of killed *staphylococcus aureus*, *albus* and *citreus* and 50 million each of streptococci, *B. coli*, *B. pseudo-diphtheriae* and gonococci. It is marketed in packages of four 1 Cc. ampules. Also marketed in vials of 20 Cc. and in 4 syringes. Syringe A being of the composition mentioned above and constituting the initial dose, while Syringes B, C and D contain, respectively, 2, 4 and 8 times the amount of bacteria contained in Syringe A. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Pneumo-Bacterin Mixed, a pneumococcus vaccine, each Cc. being said to contain 50 million killed pneumococci, 25 million killed streptococci and 50 million killed staphylococci. Also marketed in vials of 20 Cc. and in packages of 4 syringes. Syringe A being of the composition mentioned above and constituting the initial dose, while Syringes B, C and D contain, respectively, 2, 4 and 8 times the amount of bacteria contained in Syringe A. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Scarlatina-Bacterin (Scarlet Fever Vaccine), a

streptococcus vaccine, consisting of a suspension of killed streptococci obtained from scarlet fever cases. Marketed in packages of 4 syringes, Syringe A containing 50 million killed streptococci, while Syringes B, C and D contain, respectively, 2, 4 and 8 times the amounts of bacteria contained in Syringe A. It is also marketed for immunizing purposes in packages containing 3 doses ready for use and sufficient to immunize 1 person. Also in 20 Cc. vials, sufficient for immunizing 6 persons. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Typho-Bacterin Immunizing, a typhoid vaccine, marketed in packages containing 3 syringes; the contents to be injected subcutaneously at intervals of ten days. Hospital-size contain 30 ampules, in sets of three. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Staphylo-Bacterin Mixed, a staphylococcus vaccine, composed of a suspension, each Cc. containing 25 million killed streptococci, 100 million killed staphylococci and 50 million killed *B. coli*. It is marketed in packages of four 1 Cc. ampules. Also in 20 Cc. vials and in packages of 4 syringes, Syringe A being of the composition given above, while Syringes B, C and D contain, respectively, 2, 4 and 8 times the amount of bacteria contained in Syringe A. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Von Pirquet Test for Tuberculosis consists of old tuberculin in capillary tubes. Each tube contains old tuberculin sufficient for one test. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Rabies vaccine is an antiviral vaccine prepared according to the method of Pasteur. It is a complete treatment, consisting of 25 doses, to be administered during 21 days. Each day's injection is shipped in a Caloris vacuum bottle. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Bass Test for Typhoid Fever is a modification of the method of Widal consisting of a suspension or emulsion of killed typhoid bacilli, a glass slide on which to mix the emulsion with suspected blood, a slide with dried smear of infected blood, a needle for pricking ear or finger to obtain suspected blood from the patient and a pipette for dropping typhoid emulsion and water on slide, previous to mixing with suspected blood. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

Mulford's Widal Test Outfit is a means of applying Borden's modification of Widal's Test. In this test the serum of the blood is mixed with salt solution and then with a suspension of killed typhoid bacilli, so as to bring the dilution up to 1 to 50. The typhoid bacilli, so shelluetainwoxy 1 to 50. The positive reaction is determined by noting that the clumps of bacteria sink to the bottom of the test tube and leave a limpid, clear

fluid above a small, white, flocculent mass of agglutinated bacilli. H. K. Mafford Co., Philadelphia.—(*Jour. A. M. A.*, Feb. 3, 1912, p. 343).

LONGEVITY—THE WISDOM OF AGE.*

By T. J. TOWNSEND, Owensboro.

Longevity is a very interesting problem, it is a question that involves mystery and is of the highest order of importance to the thoughtful and progressive physician, and the greater philosophers are awaiting with expectation and deep concern a better knowledge for securing the envied goal of human aspirations—how to live best—how to live long and how to keep contented.

The human race is omnivorous, its food supply exists abundantly in the animal and vegetable kingdom in every part of the world best suited for the habitation of man; its general character is homogenous and complex, its society, its morals, its physical development, its genius, its health and its longevity is measured by environments.

While presenting this interesting theme for your thoughtful consideration, I am trusting to your indulgence for offering allegoric methods to clearly define and simplify in a manner to avoid the friction of monotony, I shall only hope it may contain due proportions of digestible material, and that it may furnish originality of thought that is flavored to suit the taste of culture and refinement.

When we are persuaded to accept theories of heredity and longevity that are long passed down the line of descent, we are accepting the tenets and pursuing the traveled paths of the fathers; and when we strive to feel satisfied with their teachings and declarations—or shall have yielded unto them recognition, and that we are reconciled to the common verdict of expectancy as to the average life of man—and that we are pleased with any age that equals the years of our progenitors.

Is it right for others to do all of our thinking? They have failed to say enough on the most important question that concerns you or me. Those men lived longer than men are expected to live at the present time.

If we can engage the kind of philosophy that will guide us in living a profitable life unto ourselves and unto others, if we can make it possible to escape the feebleness, infirmities, and utter helplessness of old age, it shall be regarded in the light of an extraordinary performance; and the person who has accomplished it, is gifted with some kind of superior skill for doing so. They are govern-

ed by a principle they have adopted; a habit, or precedent transmitted without any reason, or explanation, or their longevity may be accounted for because they have inherited plain food habits, and the custom of prolonged slumber from even-fall till early dawn. Early to bed and early to rise, is a good maxim. When weary from age, early to bed, and late to rise, is the accepted logical remedy.

The pulsating funis that binds and conducts the blood stream of a child newly born, when tied and severed from its maternal attachment at the time of birth, is usually attended with a startling cry: it is the voice of independence that declares it a separate being from its mother—it is the yell of triumph and the scream of liberty—it is a holy reminder of sacred, and serious obligations that involves duty, reputation, effort, affection, fear and solicitude on the part of its parents.

It is the time of supreme joy in the married relations of life, when a young mother prints her first kiss of genuine unselfish love squarely on the face of her first-born, it is the time when she looks with eager searching eyes upon a new ideal of requited love, the envied goal of human aspirations; it is when her strongest emotions are first begun, and when two beings are engaged in making the most interesting chapter of biological existence, it is the baby's cry, its dimpled cheeks, its flitting smile, its flashing dawn of intelligence that quickens the tenderest emotions of maternal pride. She would mold its form into an object of beauty, hardness and health, she would quicken its brain with intelligence, and teach it useful accomplishments, she would crown its victories with honor, would extend its years on earth, would breathe into its soul the wisdom of age, and the philosophy of life.

The day when advancing science shall have acquired satisfactory knowledge of vital chemistry as it is naturally conducted in the laboratories of the human system, and the day when it shall obtain better acquaintance with those physiological laws that harmoniously conduct the functioning organs of life, or when we shall claim satisfactory evidence of the etiology of fatal and malignant disease; that day, a grateful world will learn to bless medical science. This question is often asked by our anxious patrons. Is medicine a perfect science? Why should it forever fail to relieve a cancer, and why is an advanced case of consumption condemned and consigned to a martyr's grave?

When medical skill is so perfected that it can reach forth and promptly restore normal conditions of the human system, when intelligence and reason have engaged the assistance of vital chemistry to restore the broken balance in human economy, when we learn through diet and its chemistry how to over-

*Read before the Daviess County Medical Society.

come the acid diathesis we will then know how to extend the age of man.

How to completely cure diathesis and maintain a cure, is doubtless one of the most difficult problems encountered in the early practice of medicine. Since the days of Hippocrates, the most enlightened physicians of the world have striven to know, but no specific is yet discovered.

The contending cause at the present age, is found largely in the infected foods of the sideboard, the cellar, and the refrigerator, the unwholesome food and excessive eating leads to mal-assimilation. Acidosis is the proximate and remote cause of all diseases in which diathesis is concerned, cachexy is the fiend incarnate that is opposed to longevity.

The time is, when the wisdom of old experience shall have the tenacity to rise from its ashes, and declare its presence in the vanguard of the profession; its silence, its conservatism, its modesty should be outspoken in the advancement of science.

The lives of ninety millions of American people in health and in disease are awaiting with expectations when the distinguished councils of medical men shall offer means of relief for cancer and tubercular fever—now known to be the most dreaded foes to humanity. With blind effort to overcome an obstacle of defeat, we are becoming the passive tools of experimentation. Let us rise in our dignity and ascertain the common cause of premature deaths. Acids of toxemias rob the home of its idols, few are permitted to reach old age.

When the ultimatum is disclosed as to the most common cause of rapid decay, that the underlying principle of disease is due to the presence of toxic acids, science will arise in the light of evolution and apply the proper remedy for maintaining the normal alkalinity of the blood; expectation will then be rewarded and the average age of mankind shall be extended many years.

Then fond parents may look with renewed hope on the babe in its swaddles, wrapped and tucked away in its little bed, the child will yield a permanent contribution of happiness, nor shall it be a torturing gift of anxiety, nor sorrow, nor misery, nor disease, nor shall the mother's ambition fail to provide for and safeguard it through the dangers that hasten death; she will grow it into usefulness, and grant it a long limit of fruitful years.

The field of human knowledge is unlimited, it is beyond the acquirements of any one man, it is capable of exerting as much influence for evil, as for good; and more frequently do the appetites of men lead to indiscretions that prove hurtful to the health, and to the morals; it is also opposed to the blessings and benefac-

tions offered by those who have higher and more complete ideals of right.

A child may inherit belief and may acquire knowledge through the teachings of the parent. Two individuals may feel equally right in the conscience, but are far apart when weighed in the scales of public opinion. Theory suggests an idea—the idea is put into practice and a standard is adopted and placed to record—but when intelligence is weighed by ignorance, science is held in abeyance, progress is arrested, effort is stultified, and merit goes unrewarded.

Only the mind of experience is fully conscious of a thousand errors that can be corrected or avoided, were it not for the misguided enthusiasm of youthful ambition, harnessed with commercial energy that is hurtful to the moral and physical welfare of the human race. Age does not misapply its energy, its effort is concentrated and effective, it earns distinction and wears mantles of honor. The gray chieftain is successful in wars, in politics, and in peace. If a wise man, he is crowned with success, and glory attends him to the grave.

'Twas an old Arabian sage that watched through the vigils of the night together knowledge of the stars that light the heavens and that do silently stand guard over a sleeping world.

Great astronomers of the present century are accorded little less honor than the aged star worshippers in the long ago. The pagans have passed away and progressive nations have risen in the earth to profit by the traditions of the slumbering past, and now, the old philosopher is bending his mind to direct the sight of younger astrologers to thousands of glittering worlds hitherto unknown to the sages of ancient Persia.

The wisdom of age is a storehouse of experience that offers the greatest benefactions, it teaches prudence, skill, industry and patience, it is the mental, moral and physical guide that builds hope and nurtures ambition.

We are reminded that the wily Arab who inhabits the lonesome desert of the Orient, is possessed of a greater knowledge of the secrets of health and the mysteries of longevity than any of the class races that have grown great in the civilized world, or any other that may claim advantage of superiority for having accomplished more in the arts and sciences.

Through generations, and for centuries, the hardy children of Araby have continued to pass down to their successors, traditions and habits of living that enable them to attain the greatest possible age. It is not uncommon to see Arabians in the best of physical and mental health at the advanced age of one hundred and fifty years, subsiding entirely on cereals, camel's milk and the natural fruits of the desert.

Gentlemen, shall we advance further into the hidden mysteries of pathogenic disease, or shall we live the more contented way by ceasing to make further effort in the business we have chosen to represent?

Shall we feel content with our moorings, and shall we continue our homage to those who would make us an army of slaves, and instruct us how to use their private commercial endurances?

Could we find courage to restore our independence, and renew the prestige of the past, we would discontinue the mysterious madness of the present time and profit by the errors of the hour.

Could we employ the art of Necromancy, i. e. by calling forth the spirits of the long forgotten past, we would be led to exclaim with surprise, that while American physicians have advanced more rapidly than those of other countries, we are painfully deficient and widely apart on the question of diet, yet we see the possibility of extending the average life of man.

For the sake of all-prevailing truth, in the light and preservation of better statistics, go visit the graven tombs in our lonesome cities of the dead; go read from the stones a truthful record of the age of man, read his past and his present age, read those dates from the artful chisels, and the sculptor's hand, a history of vanished hopes and withered flowers. Then let us learn to profit by the wisdom of age, and learn to grapple with the *acids of decay*.

Only in the line of epidemics have we succeeded best in checking the fatal tendency of disease and the frequency of death; we are acquainted with contagion and infection, cause and prevention, we possess practical knowledge of quarantining the sick, but have we yet a complete knowledge of longevity and the wisdom of age?

In one particular it is unfortunate for the doctor, that all persons sick are not mentally or evenly balanced, and that below the average line of human intelligence he encounters ignorance, disobedience, skepticism, superstition, and total disregard of moral obligations, some are abandoned to the evils of licentiousness, to excesses, to exposures and dangers of infection; with this class of patients we are feeble to exercise proper control.

The monarch of the forest that has for centuries waved its massive branches in triumph overhead, is a fit example of longevity; it may attain the growth of a thousand years on account of its nature and environments; its home is stationary, and its habit is of the unvarying kind, its delving roots dig deep in Mother Earth, its food is the same kind year in and year out, its tall branches wave in majestic splendor in the open sky, its feet are

eased in the soil, in the warm springtime it puts forth its blossoms, it lives in the open air, and drinks the dew of heaven; when calm its dignity is appalling, when disturbed by the winds, it sighs and moans; its leaves tremble and flutter, they murmur and sing the sylvan songs, and whisper in our ears the philosophy of life and the wisdom of age.

The whale and the elephant are the only two animals known that possess larger amount of brains than man.

The whale is the longest lived of the animal creation, it is the monster and the monarch of the deep, its great age is due to its indolent nonlaborious manner of feeding and to its large consumption of wholesome, simple, nutritious food so abundantly supplied by its home in the sea. The capacity of its mouth offers inviting refuge and place of shelter for myriads of unsuspecting schools of fish that gather within its massive jaws, which in the large animal measures about sixteen feet in length, seven feet in width and twelve feet in height, its gullet is less than two inches in diameter, but capable of great distention. With its mouth wide open it drives and feeds through congregated shoals of lobsters, crabs, shrimps, madras and other varieties of soft fish that abundantly inhabit the sea. On its simple diet the monster will live a thousand years or more.

The elephant in its wild state will live two or more centuries, its food is the simplest known, consisting mostly of sweet grasses, the tender herbage of the forest and of the field.

Of the feathered tribe, the raven and the parrot are the simplest feeders known, they will live a hundred years. Object lessons are useful, we should turn them to good account. The longest lived birds and animals are possessed of the simplest habits. Intelligence is at war with passions. Education is overpowering ignorance; knowledge is extending the influence of reason; transgression is punished, and the wisdom of age is subservient to the health, to the happiness, and to the longevity of man, surely and slowly we are drifting in the line of progress.

The world's greatest men are being awakened to public health, interest is growing, sanitary laws are being enacted, commissions appointed, tainted food is being condemned, all for the good of mankind.

I shall not invite the question of greater evils that retard the advancement and lessens the civility of man, nor those subtle influences that affect the stability of the honorable institutions of medicine.

A human idea is conceived, it is born and acted upon, it lives and starts a habit, it offers suggestion and is a precedent transmitted, it proves a benefaction, or it may prove a

curse. Man inherits habit or precedent more frequently than he inherits disease.

The trinity of human happiness is *health, peace and competency*; its requirement is attended with self denial, patience, effort and endurance. Mammon is enriching avarice, feeding lust, and treating health with disease.

Know ye, all men who would live long to enjoy the benefactions of health and the wisdom of age. Gather knowledge from the simplest habits of the centenarian, learn it from the whales of the sea, the great trees of the forest, the mammoths of the jungles and the ravens of the air; by each one's habit, learn the value of rest and of plain food.

The hardy pioneer of early days seldom got sick, only from exposure, hunger, or fatigue; his daily food was limited to the supplies of the forest and the field, his fruits and vegetables were eaten in season, his meats were freshly served, boiled, wholesome and appetizing.

Those people who live the longest, find protection in their homes, one quiet hour of repose on a sofa each day after meals is sometimes capable of restoring in three months' time the lost energy of a dozen years. In many cases of injured health it affords the only safe and reliable means for bridging the many cases of injured health it affords the grave.

The brilliant achievements in medicine and surgery are largely credited to enforced recumbency and prolonged rest. The fame that rewards the surgeon's effort would lose its glory, his gentle hand would be divested of its magic power, his knife and his skill would fail him; the wizen den would more frequently stare him, and mark the places of early graves, were it not for his uncompromising law of unbroken rest and wholesome food. Rest is a bolster, it is the storehouse of vital energy, the logical friend of fatigue, and the lingering charm of life. Upon its benefactions depends the harmony of nature's foremost laws; disappointment, pain, sorrow, exertion, fatigue, fretfulness, anger, thirst, hunger, broken rest, exhaustion and worry: the united forces, and the constituted enemies to health and to longevity.

Now, we shall offer a few useful hints to those who lead the strenuous life, who for many obvious reasons, would keep awake at night, by drinking artificial strength from the fragrant tea, and the steaming coffees. Renewed strength is in demand, quick stimulants are strangely adapted to the desires and appetites of the human race. A stimulant dispels gloom and fatigue, wakefulness is excited, and night is converted into day; it arouses the latent powers, it spurs the languid spirits of the weary soul, the tempting

gods invite reaction; the tea, coffee and tobacco are unfortunately fitted to extend the hours of wakefulness and revelry, but nature prays and begs for sleep, it deplores the use of anything that would rob the body of needful rest, but the habit is fixed, it pacifies the mad craving of the hungry soul, and leads it to enjoy the cool shades and refreshing air of night. Mankind is surrendered soul and body to the social pleasures of night, it is the time when a stimulant is called for to elevate the jaded spirits, it tides the waves of the feeble heart, it strengthens the weary nerves, it awakens the appetites of pleasure, it is the fitful companion of joy; but alas, the unrestrained agent of habitual wear and hopeless decay.

Acidosis is the offspring of toxemia, the fateful poison of age; it proclaims its visitation and its presence with white hairs, with bald heads, with decayed teeth, with wrinkled skin and bended spine; it gathers with advancing years to mar the beauty of the form, to dim the luster of the eyes, it poisons the breath, it sickens the smile, it cracks the voice and racks the nerves, it tortures the heart, it weakens the frame, it produces tension, lessens inhibition, hardens the arteries, stiffens the joints and shortens the life of man; its factory is the human stomach, its domain is in the blood, its kingdom is the body of man; it is the arch fiend that preys on the vitals, it is the artful chemist that invites the weary traveler into the shades of eternal rest.

IRITIS AS SEEN AND TREATED BY THE COUNTRY PRACTITIONER.*

By J. F. DUNN, Arlington.

Unfortunately for our patients we have no specialist near by to whom we can refer our eye patients, therefore, we are compelled to rely on our own responsibilities, giving them the benefit of our general knowledge, by the aid of our medical literature, and trusting our old friend Nature for the balance. Ofttimes we are compelled to treat diseases of the eye with reluctance, feeling our incompetency, but the patient frequently is not financially able to go away to a specialist and prefers to stay at home under the care of his family physician and risk the consequences.

Iritis is one of those diseases which confronts each and every one of us occasionally. It is of supreme importance that we make an early diagnosis and institute proper treatment, for in no other disease is delay or neglect more detrimental.

Iritis is an inflammation of the iris, often involving the ciliary body and choroid. It may be plastic, suppurative, or serous. I shall not take up each type separately as one usu-

*Read before the Carlisle County Medical Society.

ally merges into another but shall take up the subject as a whole, as it all amounts to about the same.

PATHOLOGY.

This is similar to inflammation of any other part of the body. The iris is congested, thereby, causing the discoloration and slight swelling. It is the swelling of the iris which causes it to encroach slightly on to the pupil, thereby making it smaller than normal also smaller than in the other eye if only one eye be affected.

As soon as plastic exudate is thrown out at one or more spots on the posterior surface, and it is at these points that the iris adheres to the capsule of the crystalline lens, a condition known as posterior synechiae. Occasionally adhesions take place between the anterior surface and the cornea, known as anterior synechiae. It is these conditions that make the prognosis gloomy.

The disease usually lasts from two to four weeks, and, in the writer's estimation, if the proper treatment is applied very early and continued, the majority of cases will recover.

Exclusion of the pupil may result, because of extensive adhesions, which by preventing the escape of fluid from the posterior into the anterior chamber, cause glaucoma.

Occlusion of the pupil, as a result of lymph deposit in the pupil may cause total blindness.

ETIOLOGY.

Fifty per cent. are due to syphilis, either acquired or inherited. Rheumatism, gout and traumatism are also frequent causes. Of the few cases that have come under my observation, traumatism was the most frequent cause.

DIAGNOSIS.

There are two other diseases that are some times liable to mislead us, viz.: conjunctivitis and glaucoma. We can very readily distinguish them by the following points.

Iritis: Pupil small and dilates irregularly by use of a mydriatic; lacerimation but no discharge; pain, radiating to temple and cheek, becoming worse at night.

Conjunctivitis: Pupil normal and dilates readily and evenly; mucopurulent discharge; no real pain but hot gritty feeling.

Glaucoma: Pupil widely dilated and immovable; lacerimation; severe pain and headache which are constant.

Henceforth, when a patient comes to you with a red eye, with profuse lacerimation, severe pain radiating to temple and cheek, becoming worse at night, the pupil being small and gray and upon the application of atropine it dilates slowly and unevenly, you will rarely, if ever, miss it when you call it Iritis. And you should put him on prompt and active treatment—which should be as follows:

Give a calomel purge as a routine. Ascertain the cause which, if it be syphilis, put him on mercury. If it be gout or rheumatism, put him on salicylates. If it be due to traumatism remove the foreign bodies, if there be any, and cleanse. At the earliest possible moment put the eye under the influence of a mydriatic, the best of which is atropine. This should be used unsparingly till the pupil is widely dilated, then only often enough to cause it to remain so until all the inflammation has subsided. A little cocaine may be added for relief and also for the aid it affords the mydriatic. Boric acid solutions are good for the antiseptic effect although I find no author to bear this out. Sajous recommends very highly scopolamine hydrobromate, using two drops of a one-tenth of one per cent. solution three times daily, which removes synechiae that atropine fails to influence. He says it quickly removes the pain. In a long continued case he alternates it with atropine.

The general nutrition of the patient should be looked after, consequently, it is not best to confine the patient to a dark room for too long a period as we will deprive him of Nature's best tonic—fresh air,—but we can overcome the photobia to some extent by dark glasses.

Moist, hot applications help to relieve the pain and inflammation. In traumatic iritis cold applications are recommended. Reading should be prohibited and the patient put on a light, wholesome diet.

I have had to resort to the use of opium in some form for the relief of pain.

For the sequels of iritis, such as exclusion of the pupil, occlusion of the pupil, corneal opacity or glaucoma, iridectomy has to be performed. When this is the case we, as country practitioners, should send them to a specialist or let them alone.

ABORTION.*

By M. A. LEXTON, Lookout.

By abortion is meant the interruption and termination of pregnancy by the expulsion of the ovum before the end of the twenty-eighth week of gestation.

In a more restricted sense, the term is used to denote the expulsion of the ovum prior to the complete formation of the placenta, that is, before the twelfth week.

Miscarriage would mean the expulsion of the ovum from the twelfth to the twenty-eighth week. While expulsion of the fetus between the twenty-eighth week and a short time before full term is designated premature labor.

*Read before the Pike County Medical Society.

FREQUENCY.

Statistics relative to abortion are far from complete. Many abortions occur during the first three months of pregnancy that physicians have no knowledge of, and it is more than likely that prior to the third month, a great number take place that are not suspected by the patients themselves.

The frequency of abortion to labor at term has been variously estimated by different authors as 1:5 1:2 and 1:8. Some investigators claiming thirty-five to forty out of one hundred mothers abort at least once before their thirtieth year.

There are more abortions during the first, second and third months of pregnancy, due perhaps to the great vascularity of the uterine mucous membrane, also to the feeble attachment of the undeveloped chorionic villi to the decidua, and to the existing space between the chorion and decidua reflexa.

The accumulation of blood in this space is no doubt an exciting factor in causing abortion. The disposition to abortion diminishes after the fourth month, as the placenta becomes more fully developed and the connections between the ovum and uterus becomes stronger, the uterus adjusting itself to the new order of things.

Abortion is more likely to take place upon the days corresponding with the menstrual period.

ETIOLOGY.

Abortion is more likely to take place upon death, or of uterine contractions. The causes are usually subdivided into those referable to the father, to the mother, or to the fetus and may be either predisposing or exciting. Exciting causes act more quickly, such as blows, falls, jarring, missteps, lifting heavy weights, stair climbing, etc. The predisposing causes may be paternal or maternal. A syphilitic father may produce syphilis in the ovum without infecting the mother. Extreme youth, old age, debauchery, and feebleness are also paternal causes.

Tuberculosis and syphilis of the mother may destroy the fetus by transmission of these diseases, either to the placenta or ovum.

Syphilis being responsible for the majority of recurring abortions.

The acute infectious diseases kill the fetus, either by the direct action of poison through the placenta, by the action of high temperature, or by placental hemorrhage produced by the disease process.

Diseases of the heart, lungs, liver and kidneys destroy the fetus by producing congestion in the placenta. Chorea, eclampsia, epilepsy, vomiting, coughing, fright and anxiety are all factors in the causation of abortion.

SYMPTOMS.

Reliable signs and symptoms of approaching abortion rarely exist before the third month. Simple uncomplicated abortions occurring before placental formation are quite frequent and probably does not represent the class of cases coming under the physician's care. As a rule, abortions are slower than normal labor at term, the abortive process varying according to the period of gestation, the cause of the abortion, condition of the os and cervix and energy of the uterus.

In early abortions, hemorrhage is the leading symptom and usually the first to attract attention. Generally the hemorrhage will continue until the uterus is empty.

After the fourth or fifth month the symptoms resemble labor at term.

Here the hemorrhage may appear only at intervals in the shape of clots, collecting in the uterus in considerable quantities before being expelled. This is termed "concealed hemorrhage." After the fourth and fifth month the pains of abortion resemble labor at term. At times, nature comes to the aid of the patient and completes the case nicely. Usually this is not the case, for owing to the firmer connections to the uterine surface, more force is necessary for detaching the membranes. The amniotic sac usually ruptures and the fetus is expelled.

Instead of the membranes and the placenta coming away with the fetus, a portion or all may remain behind, requiring days, weeks and even months for completion.

This is termed, "incomplete abortion."

So long as any portion of the ovum, or its coverings, remain in the uterus, just so long will the patient be subjected to the risk of hemorrhage and sepsis.

Pregnancy existing and abortion determined upon as the cause of the symptoms, the next thing to find out, is whether abortion is simply threatening, whether it is inevitable, or whether it has been completed.

In threatening abortion, the os and cervical canal is not dilated, the hemorrhage not profuse and the pains are easily controlled.

In inevitable abortion, the os is dilated sufficiently to admit the index finger, and the uterine contents are forced down within reach of the finger with each pain, hemorrhage and pains cannot be controlled. Abortion is complete when the uterus is free from avular tissue. Incomplete while any portion remains behind.

The continuance of pains or of hemorrhage, or both, is evidence that abortion is not complete.

TREATMENT.

In the treatment of abortion we have to consider: (1) prophylaxis; (2) treatment of

threatening abortion; (3) management of actual abortion; (4) treatment of incomplete abortion and after management.

The prophylaxis consists in the treatment of all those general and local conditions which predispose the patient to abortion.

In threatening abortion, if the os is found undilated, hemorrhage slight, pains moderate or absent, the case should be treated as preventable.

Our aim should be to prevent, if possible, any further separation of the ovum from the uterus, by endeavoring to control hemorrhage and prevent uterine contractions.

The patient should be put to bed, absolute quiet and rest maintained for several days until all danger is passed.

In the way of drugs, opium in one of its forms meets the indications as a sedative. It should be given often enough to preserve systemic quiet. If it is thought necessary, the bromides may be given in place of the opium, or given in connection with it. The fluid extract of viburnum in drachm doses, seems to act nicely in quieting uterine contractions.

Treatment of inevitable abortion. If the os is dilated, pains and hemorrhage continue, notwithstanding treatment, the indications now will be to control hemorrhage and secure complete evacuation of the uterus.

Before the fourth month, the vaginal tampon will control hemorrhage and hasten the complete separation of the ovum by causing an accumulation of blood between the uterus and the membranes. The tampon causes strong uterine contractions. The material used may be strips of antiseptic gauze, strips of sheeting, cheese cloth, roller bandage, etc.

The tamponing may be done with the aid of dressing forceps and one or two fingers as a guide.

Care should be taken to pack well about the os and cervix. The tamponing is continued until the vagina is moderately filled, a pad is placed over vulva and held in place by a T-bandage. Half drachm doses of the fluid extract of ergot is given every two hours.

If there is much pain, five grains of phenacetine will give relief. After from eight to twelve hours the tampon is removed, usually the entire ovum, or the fetus alone will be found in the vagina. If only a portion is thrown off, we should tampon again.

If this is not successful, the uterine cavity should be explored with one or two clean fingers, the retained portions separated and removed. If unsuccessful with fingers, use a curette, or placenta forceps, followed by the curette and a hot saline douche of normal salt solution, a one or two per cent. creolin solution, or a hot solution of permanganate of potash, drachm to pint, acts nicely.

Treatment of incomplete abortion. If af-

ter the apparent completion of abortion there is hemorrhage, continuous or interrupted, with pain and odor of decomposition it is certain some portion of the placenta or membranes remain behind.

The indications are clearly to empty the uterus completely, and at once, with fingers if possible, with curette is necessary.

This is followed with a hot intrauterine douch, and repeated every six to twelve hours according to indications.

A woman who has aborted requires as much time for the repair of lesions and involution of her enlarged uterus as does the woman who is delivered at full term.

If this was generally recognized, there would be a marked decrease in the number of pelvic disorders, and there would be as great a falling off in the number of abortions.

RHEUMATISM.*

By T. C. NICHOLS, Morgan.

An acute infectious disease, characterized by fever, inflammation in and around the joints, acid sweats, and a great tendency to inflammation of either the endocardium or pericardium. The disease is believed to be of infectious origin, but no specific organism has as yet been isolated. The tonsils are very often the portals of entry for the infection. Certain predisposing factors seem necessary for the production of the disease. Among these may be mentioned exposure to cold and wet, sudden reduction in the temperature, lowered vitality from various causes, winter and spring seasons, heredity and previous attacks. Acute rheumatism is a disease simulated by other infectious fevers especially scarlet fever, puerperium and gonorrheal synovitis due to a specific cause or a remote consequence of them. The affection is seldom observed before seven or after fifty years of age. The affected joints are intensely congested and the synovial membrane and surrounding ligamentous tissues are greatly swollen. The cartilage may be eroded. The synovial fluid is thinner than normal and of a reddish color, containing albumin, some gelatinous coagula of fibrin, leucocytes, but no pus cells or organisms in simple cases. There is an increase in the quantity and in the number of white corpuscles in the blood. The inflammatory edema of the joint and adjacent structures gives rise to considerable visible swelling and by its stretching of the parts and pressure on the nerves induces, in all probability, the pain. The joint condition usually ends in resolution. The complications of this affection possess no features different from the same conditions

*Read before the Pendleton County Medical Society.

when occurring independently. Usually the onset is abrupt, there is more frequently a short prodrome of a day or two, during which the patient feels uncomfortable or has an unpleasant aching feeling in his joints. More often, however, the pain in the joints, which is the first symptom to attract attention, develops rapidly, coming on in a single day or night, or seemingly in much shorter time, making locomotion at once difficult or impossible. After the affection has begun, there are profuse acid sweats, great thirst, constipation, and scanty, high-colored, acid urine containing an excess of uric acid and urates, and sometimes traces of albumin. From the beginning there is fever, but being seldom high at this stage, it is not commonly the first symptom to attract attention. Later, it usually increases proportionately to the extent of joint involvement, but only in the meningeal form is it extremely high. Nor does it pursue a course at all distinctive. Occasionally, however, there is intense hyperpyrexia, when the temperature rises rapidly from 104 degrees to 110 degrees F., and even higher. With this are associated cerebral symptoms of an alarming and dangerous kind intense headache, and delirium, symptoms otherwise rather unusual in acute rheumatism. To these are often added unconsciousness, pulselessness, and cyanosis rapidly followed by death, unless the temperature is promptly reduced. This combination of severe symptoms is known as the meningeal form or rheumatism of the brain. Sleep is prevented by the pain and the profuse perspiration. The strength is moderately well preserved. The skin is covered with various forms of miliaria or prickly heat due to excessive irritation of the sweat glands. The local phenomena are pain, increased by motion and pressure, tenderness, and increased heat, swelling, and redness of one or more joints. Swelling is most apparent in those joints not covered by muscles as the knee, wrist, elbow and the ankle, and is proportionate to the acuteness of the attack. The inflammation may suddenly cease in one or more joints and abruptly appear in others. The disease is extremely irregular as regards the number of joints affected, although the local manifestations are controlled by an important pathologic law, the law of parallelism. The affected joints are either on one side of the body; or those on both sides that are analogous as the knee and elbow, wrist and ankle, hip and shoulder, are attacked together. This migrating character of the inflammation is especially distinctive. In some cases the affection is unattended by articular manifestations. The most common complications are endocarditis, pericarditis, myocarditis, cerebral endarteritis, pleurisy, perito-

nitic, bronchitis, pneumonia, tonsillitis, hyperpyrexia, erythema, oedema, uteraria, and purpura. As sequels may be mentioned chorea, acute nephritis, false ankylosis, chronic rheumatism and exophthalmic goiter. The duration of acute rheumatism is governed entirely by the presence or absence of complications. Uncomplicated cases recover in from thirteen to twenty-one days, although they may be prolonged to five or six weeks. Relapses are frequent. A typical case cannot be mistaken for any other disease, but cases running a sub-acute course may be mistaken for acute rheumatoid, arthritis, gonorrheal rheumatism or pyemia. Acute rheumatoid arthritis attacks one joint at a time, becomes permanent, has slight, if any fever, and no sweats or cardiac lesions. Gonorrheal rheumatism is associated with a gleet discharge, or follows the sudden cessation of an acute or subacute gonorrheal attacks. Pyemia is usually manifested in a single joint at a time, and is followed by all the symptoms of hectic fever and suppuration.

Recovery is the rule in uncomplicated or cerebral endarteritis, one attack predisposes to others. In all cases the patient should be placed at absolute rest in bed. He should wear woolen garments, and blankets should constitute the bed clothing, care being taken to protect the inflamed joint from excessive weight of the coverings. The diet should consist of easily digested substances, preferably milk. The free use of water, particularly the alkaline mineral waters, should be encouraged. In strong and vigorous patients the administration of one of the salicylates, or salicynes, aspirin, salol, salaphen, or oil of wintergreen, may be used and pushed to the point of tolerance. In all cases, special internal treatment should be preceded by a course of calomel followed by a saline laxative. Usually this treatment affords rather prompt relief, but if after three or four days' trial there is no benefit derived from it, alkaline treatment should be substituted. This consists in the administration of an ounce and a half of one of the alkaline carbonates, either alone or combined with a vegetable acid, every twenty-four hours until the urine becomes neutral or alkaline, when the quantity should be reduced to an amount just sufficient to maintain alkalinity. After the acute symptoms have subsided, Basham's mixture or tincture of the chlorid of iron should be administered. A pale, feeble and anemic patient, strychnine sulphate and liquor ammonii acetate should be given with the iron. In all cases quinine sulphate in large doses daily, is of great value especially when there is hyperpyrexia under which circumstances it should be administered hypodermically and accompanied by a cold or tepid bath or wet pack.

For the relief of pain, opium in some form

or atropin sulphate hypodermically, alone or combined with morphia. Rest of the affected joint is essential. The inflamed parts should be wrapped in cottonwool or flannel saturated with lead water, lanadum, oil of gaultheria and compound soap liniment. If the joint condition tends to persist, equal parts of mercurial ointment and the ointment of belladonna will be found of great value. Baking the joints in a hot air apparatus is also beneficial.

THE RELATIVE DUTY OF THE TEACHER.*

By PROF. C. E. DUDLEY, Earlington.

The purpose that brings together to-day the various professions to consider the public health, is a laudable one. It is the one interest that touches the community as a whole and the one subject, if promoted, which adds to every other interest.

The medical profession offers to a man a great field for usefulness. He is not the greatest doctor who can cure stubborn diseases, but he who has the ability to teach a community how to live without disease. This is your and our mission to-day.

SCHOOL, DEFINED.

No one term has undergone a greater change in the past decade, than the purpose of the school. The one idea of the school, of our fathers and of many of us, was to teach how to read, to write, to spell and to cipher a little. The one dominant thought was to develop the intellect, and often at the expense of everything else. How different to-day. The whole child must be considered, intellectual, moral and physical with strong emphasis on the physical, as well as on the moral. In the words of Dr. Dewey, it is the purpose of the school to fit the child for complete living. Without health this is impossible, therefore the importance of the school doing its duty along this line.

EFFICIENCY.

Conservation of our natural forces and resources is one of the great problems of the day. How to prevent unnecessary losses and save resources for generations yet unborn, is a problem of sufficient magnitude to stagger the intellect of our greatest statesmen. Yet, as Ex-President Roosevelt has said, "The conservation of our National resources is only the first step in the still larger question of the conservation of national efficiency." The Nation's health is the Nation's wealth, and the mightiest need and cry of the age is hygienic and medical inspection, education and super-

vision in factory, home, store, school and college. The lack of which to-day is costing us billions of wealth.

STATE'S LOSS.

In no department of our economy is the money spent by the state, spent with so little regard for return as that spent for education. While teachers are the poorest paid of all public servants, yet if that small sum was spent under more favorable conditions, if the state should spend one-half the sum it now spends for education, to improve the physical condition of children the other half would yield a larger return than the whole does to-day.

DEFECTIVES.

This brings us to a discussion of defectives. It has been my observation that teachers readily attribute slowness or lack of ability to do work on the part of children to natural dullness or lack of brain power. While this may be true in some few cases, yet a large per cent. of cases thus attributed are due to physical defects. It has been estimated that 65 per cent. of all children entering school are unfit for successful work. While the loss from general bad health is large, yet there is a greater loss from specific causes, defects in hearing, sight, teeth, enlarged tonsils, adenoids, catarrh and other ailments are recognized to-day as the causes for slow progress in a large class. I have noted the listless, backward, pupil for years, and have come to the conclusion that the slowness is due, in a large per cent. of cases to one of these causes.

A recent investigation in Manhattan Borough, N. Y., revealed the following facts: out of 275,641 cases of school children examined, 71.1 per cent were found to need treatment of some kind, 21 per cent. had defective vision, 15 per cent. had obstructed nasal breathing, 49 per cent had bad teeth, 27 per cent. had enlarged tonsils, 16 per cent. had nasal growths, with one to ten per cent. with other ailments.

Now the children of New York are no worse off than ours. Out of 20,000,000 children in the United States in school, 14,000,000 need treatment. A little matter of personal observation last fall revealed the following: Out of 100 cases whose teeth were examined by Dr. Baldwin, 70 were found to be in need of immediate attention. All these things indicate at how great a loss our schools are operated. More than one-half the energy expended by the teaching force is lost. What is the remedy?

MEDICAL EXAMINATION FOR SCHOOLS.

This is the only solution. Parents are often ignorant as to their children's conditions, or blinded by their daily contact with them. Only an examination made by a competent

*Read before the Hopkins County Medical Society.

doctor, who can see the defects and suggest the remedies. Medical inspection helps to eradicate communicable diseases, but only a thorough examination can advance the cause of education by removing defects, medical inspection is being carried on in various parts of the world with success.

Japan has 2000 medical men who devote their whole time to the schools; New York City employs 150 physicians; Chicago has 100 medical men who look after the health of the children in schools; Minneapolis has made a good beginning by employing 8 physicians and 8 trained nurses, who visit the various buildings and render assistance where the need is greatest. And twice each year the physicians make a careful study of each child. We may be far from this in Kentucky, but the time is not far distant when the physical welfare will be considered one of most importance to the state. One great good is being accomplished through our mothers' and parents' meetings, by bringing the home and school closer together. The teacher, if sincere and competent may be able to render valuable assistance by helping parents to a better understanding of the child's physical condition and by pointing out the way to its relief.

COMMUNICABLE AND PREVENTABLE DISEASES.

The school still has a duty toward the public in its instruction and attitude toward communicable and preventable diseases. Here again the school may serve the state. During 1911 more than 5000 deaths occurred in Kentucky from contagious diseases and still another 5000 from tuberculosis. Through proper instruction in the school this number may be greatly reduced and life and wealth saved to the state. The loss through this class of diseases, to the state is immense in wealth, yet even greater in loss through its citizens. Proper instruction on the part of the school along the line of cleanliness, ventilation and exercise will make consumption a thing of the past, and care on the part of the citizens will reduce many communicable diseases to the minimum.

We represent here to-day three great professions, each deals with the public for the public good. The Doctor, the Minister of the Gospel and the Teacher. Each thinks he labors in a distinct field of usefulness, but when analyzed it reveals the fact that we all work for the public welfare.

The school to-day is trying to measure up to its duty, and in the near future I believe the doctors will find the school to be his most valued colleague in maintaining public health.

ILEO-COLITIS.*

By A. T. BORTS, Glasgow.

Ileo-colitis is an inflammation of the ileum and upper part of the colon, characterized by frequent discharges, tenesmus, with bloody stools consisting mainly of mucus.

ETIOLOGY.

Most cases occur in hot weather and in children from six to eighteen months old—second summer. Most cases occur in bottle-fed babies, and those cases not in the bottle-fed class are nearly always babies who have been allowed improper food, and if you inquire into these cases the mother will tell you that they allow the child to eat any old thing that they have on the table. So that the child's digestion is already deranged from improper food and when the depression from the hot season comes on and the unsanitary conditions that prevail in many of these cases, we need not wonder at them having trouble. It is frequently a termination of gastro-enteritis or of cholera morbus. It is most prevalent among the poor. Sudden changes in temperature will also cause it. The bacterial findings are numerous, but no one alone has as yet been identified as the cause. The Shiga-Flexner bacillus has been found in most of the cases. Pus germs are also found in the severe cases.

PATHOLOGY.

In mild cases the mucous membrane of the bowel is congested and swollen with the solitary follicles and Peyer's patches more distended, the disease may end here, but if it continues after the second week, the solitary follicles and Peyer's patches become ulcerated with decided thickening of the walls of affected bowel.

SYMPTOMS.

The acute form may develop slowly with restlessness, or suddenly with high fever, loss of appetite, thirst, nausea, vomiting, abdominal pain and diarrhoea. The abdomen is swollen and tender. The stools are semi-fluid, greenish, acid, with mucus and undigested casein. The temperature and pulse are accelerated and emaciation is rapid. Sometimes it begins as gastro-enteritis, and the transition from gastro-enteritis to ileo-colitis is so gradual as to be hardly perceptible. In the chronic form the temperature is frequently subnormal followed by sharp rises and when the bowels are moved there will be a large quantity of foul mucus. The extremities are cold, the features sunken. The skin hangs in loose folds and the child is reduced to a mere skeleton.

*Read before the Warren County Medical Society.

PROGNOSIS.

Prognosis is favorable when the treatment is prompt and appropriate, but so many are neglected, and when you are called you often find that all the colic and diarrhoea cures have been exhausted before you are summoned, and as nearly all of these patent medicines contain opium and some of them even capsicum. So that when these things are given to bind up the bowels, that are already full to overflowing with fermenting food and bacteria, it is no wonder that some of these cases do badly in spite of our best efforts. These cases are often in a subacute or chronic form when we are first called to see the child that is as they tell us, over the phone, only teething. Teething with the laity is blamed for about as much as is gripe and malaria with us doctors. The acute cases usually subside in from ten days to two weeks. The chronic form lasts from one to three months. Vigorous children who have passed their first dentition, are much more likely to get well, than those weakly infants who are surrounded by unhygienic conditions, as is so apt to be the case in the poorer classes. It is in this class of cases that the mortality is greatest, as it is almost impossible to impress on those in attendance the importance of cleanliness and to get them to feed the patients properly.

PROPHYLAXIS.

It is our duty as physicians to warn mothers, and especially those of the poorer classes, of the value of cleanliness in preparing and in keeping the food, also of cleanliness of the patient, and surroundings. Keep the flies away from the patient and its food. Give the child a daily bath. Avoid sudden chilling of the child, also see that it doesn't get too warm. See that it is not fed a little of everything that the rest of the family eats. To sum it up see that it has nothing to lower its resistance, (easier said than done), as the hot weather is enough, without having the child's digestive system upset by over-feeding, etc. We often see bottle-fed babies nursing through a glass tube with a piece of rubber tubing attached, the whole thing several inches long, and a matter of impossibility to properly sterilize them. The man that makes them ought to be hanged and then we would lose fewer innocent babies. How often do we see milk vessels hanging out in the sun and flies swarming over them? And when they are used again, sometimes they are rinsed with cold water and sometimes used without washing at all. In this way, I think, a good many are infected with not only this disease, but with typhoid, and other diseases.

Another thing I think we ought to warn people against, when we see them do it, and

that is the practice of giving coins to babies, for they don't know how many dirty pockets these coins have been in, so they don't know any better than to put them into their mouths.

TREATMENT.

Stop all food at once, and allow absolutely nothing unless it is boiled water during the first twenty-four hours. Then begin with Barley water, or rice water, if the child tires of this cereal diet, we may add a little mutton or chicken broth (free from fat) till it can begin taking milk. We should not begin the use of cows' milk till after the stools have been normal for a few days. As these cases bear fats badly, we should give skimmed milk or buttermilk. In any of the late text books on diseases of children we will find formulas for modifying the milk as the case demands. Sometimes we will find that cows' milk in any form is badly borne, so in some of these cases I have been forced to use condensed milk or some of the ready prepared foods, as malted milk, peptogenic milk powder or Mellin's food. In any case we have to be very careful in returning to a milk diet, and add it to the other food in small amounts and very gradually. When first seen the child should be given sufficient castor oil to thoroughly clear the bowel of all fermenting food, aided with thorough irrigation of the colon, through a large catheter. After the bowel has been thoroughly cleansed, then give ten grains of s. n. bismuth every two or three hours, and if it is not converted into the sulphide of bismuth as shown by the dark or black stools, give 1 grain of sublimed sulphur with each dose. In giving these large doses of bismuth, be sure you give it pure—either Merck's or Squibb's—as you might get arsenical poisoning from an impure bismuth in these large doses. If the child is still very restless and there are frequent stools, give a small dose of Dover's powder, or paregoric to quiet the child and the excessive peristalsis. Also give from two to seven or eight grains of tannin or tanalbin every three or four hours. If the child becomes drowsy and the fever runs up, leave off the opium and repeat the oil. Give also small doses of bichloride of mercury three times daily in the protracted cases till the character of the stools is changed. In bottle-fed babies, if possible, procure a good wet nurse. And in all cases instruct the mother or nurse not to let the child nurse or feed it every time it cries or frets as the child frets from thirst. It is best to boil all water, that is given the child. Our attention should be early directed to the extreme prostration, and where it is well borne, give brandy or whisky to overcome it. We should not keep up daily irrigations too long as some authors claim

that will keep up the mucous discharges. In protracted cases we can try astringent injections as 1 oz. of witchhazel to the pint of water or we might use a very weak solution of nitrate of silver as an injection. In the chronic cases I usually give a very small dose of nitrate of silver three or four times a day for its local effect on the mucous membrane of the entire digestive tract and think I have saved some bad cases by its use. In cases with bowels badly swollen, I usually irrigate with a solution of peroxide of hydrogen. In severe cases with high fever why not use proctocolysis, the continuous use of saline solution as we do in other severe infections. I intend to try it in the next severe case I have, especially if I can have the cooperation of a good nurse to use it. In the chronic cases, see that there is at least one good free bowel movement in every twelve hours, and use your best efforts to keep the child from starving, as we have to fight malnutrition as well as the disease and if the family can afford it, recommend a change of climate. If they cannot send the child away try to keep it alive till the climate changes here—that is till cooler weather—and many apparently hopeless cases will then get well. But owing to their lowered resistance they will have to be extremely cautious the following winter or the child will die of bronchopneumonia. In older children who still have dysenteric discharges of blood and mucus or pus, examine them with a speculum and if you find an ulcerated rectum treat them locally with nitrate of silver. Also in these very chronic cases, when it seems that you cannot relieve them with ordinary method try giving large enemas of from 1 to 500 to 1 to 2,000 of quinine bisulphate or if this is not effective, try Dr. Hanes' coal oil treatment, and if the dysenteric discharges still persist, especially in older children and an examination of the stools show ameba, demonstrating beyond all doubt that it is a case of amebic dysentery, we may, if the child's strength will permit, consider the advisability of doing an appendicectomy and irrigating through the appendix. In dysentery, the serum treatment is still on trial, but with one observer the use of Shiga's serum, reduced the mortality from 34 to 9 per cent.

In conclusion will say that each case is a law unto itself and should be treated as such. In this paper I realize I have recommended several remedies, but when we get a bad case if the patient lives and the family's patience holds out, we will have ample time to try different treatments. If seen early the clearing of all irritating matter with a large dose of oil, with the bismuth and tannin and a few good irrigations and careful dieting, with the addition of citrate of soda, 15 to 60 grains a day, in the milk, (when it is begun),

will cure most cases. It is the chronic cases with malnutrition, and that have been early neglected, that give us so much trouble.

THE OPEN TREATMENT OF RECENT FRACTURES.*

By B. F. VANMETER, Lexington.

The open treatment of recent fractures is a comparatively new surgical field, and has many questions yet to be answered by discussion, and a fuller experience. The experience of most surgeons in the open treatment of fractures, is limited to do so few cases that it is unwise to base an opinion upon any one man's report of cases, as a report of a half dozen or so fortunate cases is liable to lead one astray and make him think it is easy work, when in reality it is the very opposite.

The open treatment of a given fracture should not be considered, unless one has, first: modern hospital facilities; second, very reliable assistance; third, proper instruments, (which unfortunately are of a new design, are expensive, and not to be found always at hand) this work cannot be done by the surgeon alone, he must have at least four hands, (six preferred) two of his own, and two of an assistant, competent to work coordinately with his own.

Have you ever found a more difficult thing to do, or have an assistant do for you, than hold a leg or foot, in a given position for a considerable length of time, without any change in position?

The control of all hemorrhage is very necessary, and in certain fractures is exceedingly difficult. Sepsis takes away almost all chance of a good result, endangers a leg or arm, and even the life of the patient. It has been shown that the more done by long handle instruments to facilitate keeping the hand out of the wound, the better the chance for a sepsis.

Mr. Lane, the originator of the Lane bone plate, claims to do his work without touching the wound with his hands, even though gloved. I noticed at the last Clinical Congress of Surgeons of North America, held in Philadelphia, they all seemed to be striving for this technique. The advent of the Lane bone plate has practically eliminated all indication for wire. Ivory pegs at the neck of the femur, and humerus, and in old and ununited fractures of long bone, where the medullary canal has been closed by hard sclerosed bone, ivory pegs, or nails are a necessity.

Hard sclerosed bone unites to sclerosed bone with difficulty, if at all. I have recently

*Read before the Kentucky Midland Medical Society, Georgetown, April 1, 1912.

had a case of this character, where the union was not quite firm, after three months the medullary canal was closed by hard sclerosed bone, and it should have been bored out at each end, and in addition the Mayos follow the practice of inserting a foreign body in the form of an ivory peg, claiming an increased leucocytosis, and increased healing.

There is great debate as to choice of time to operate, some claim after several days is the choice time, others claim in the first twenty-four hours, or as soon as the patient can be prepared. I see no good reason for this last contention, the first allows far more consideration of the case, and the better judgment, and it is certain that we need all judgment we can get, in deciding to operate on a recent fracture, it allows for recuperation from shock, cessation of hemorrhage and the study of possible X-ray pictures.

Compound fractures should not be plated, they should have all foreign matter removed with sterile forceps, all shreds and devitalized tissue cut away with scissors, no shaving, no washing, no loose stitches, then dressed with moist carbolized gauze, and put at rest. Under this treatment, many primary unions will be obtained. After the primary union, the treatment of the fracture can be as necessity indicates.

In practically all ununited fractures the open method of treatment with the Lane bone plate is indicated, there would be fewer of those to treat if it were possible to obtain X-ray pictures and subject the fracture to adjustment, and plating, as soon as it is definitely determined that a functional result will not be obtained; this being done before the muscle contracture will make it necessary to sacrifice length of limb. In some cases the open treatment, might be indicated for cosmetic reason, entirely aside from function, after the patient has full knowledge of the risk involved.

It is not my intention to go into details of various fractures of the bone which could or should not be treated by the open method. I think it would confuse the few points that I want to bring before you. I will say, however, that depressed fractures of the cranium and fractures of the patella, should practically always be treated by the open method. In fractures of the humerus, especially spiral fractures, and fractures of the lower and middle third, and fractures of the lower third of the leg, both bones, are the most frequent sites that bring forward the indication for the open treatment. As for myself, I think fractures of the lower third of the leg, both bones breed disaster, and are among the most difficult to get good results with splints, the difficulty increasing with the proximity of the fracture to the lower end. In this area plat-

ing is most easy, but it must be said, however, that the tibia has less toleration for plates than almost any other bone; this is attributed to its superficial covering.

Admitting that we have proper equipment and conditions favorable to do this work, there are a few questions that we must answer in each individual case before advising the open treatment in recent fractures; first, what is the chance of getting a functional result by splints; second, what is the personal equation of the patient as a surgical risk; third, what are the chances for a good functional result by the open treatment; fourth, what additional risk does the patient pick up by the open treatment?

The dangers are, anesthesia (which would probably be in either case), hemorrhage, involvement of the heart, kidneys, and lungs, shock and sepsis, in the reverse order named. The danger of embolus must be mentioned, and is probably a little accentuated by the open method.

Where the wound is closed the plates have to be removed later, rather too frequent for the peace of mind of the surgeon. The closer the plates are to the surface, the more often their removal becomes a necessity. In seeking figures on the subject, it seems this necessity occurs about one time in five, in the hands of very experienced men. A great man of experience, Mr. Lund, reports eleven cases, and was obliged to remove four plates.

You have probably reached the opinion from the foregoing, that I am not an enthusiast for the open treatment of recent fractures. Why? Because, after looking over the rather voluminous recent literature on the subject, and having had a limited personal experience, I do not believe that Mr. Lane's position, where he advocates the open treatment of practically all recent fractures (where there is no contrary indications of a constitutional nature) is most radical, to the extreme of foolishness.

If all of us had not had many good results, or I might say perfect results, by the old and time honored use of splints, accompanied by traction, we might be a little more tolerant of Mr. Lane's extreme views.

We all know that in the vast majority of fractures with an accurate diagnosis, a fair knowledge of anatomy, coupled with a reasonable amount of common sense, that we can get good results, with a minimum of risk to the life and health of the patient.

I want it understood, however, that with a patient that is a good surgical risk, the open treatment would be advised as soon as it becomes very doubtful that a fair result can be had by splints.

There is a class of fractures where we have never gotten good results by our old method

of treatment that carried with them a mortality above sixty per cent. I refer to fractures of the base of the cranium. Here the most radical treatment becomes a virtue, and until Harvey Cushing, before the Southern Surgical Association in New Orleans, in 1908, brought forward the theory as to the cause of the high mortality in fractures of the base, and propounded his theory of decompression, these cases died in an obscure corner of the wards of our hospitals, their only treatment being calomel or croton oil, or both.

Cushing first asked the question, why should there be such a high mortality in a simple linear fracture with practically no displacement.

When one remembers that the brain fits accurately, and fills completely the rigid and unexpandable cranium and at the same time calls to mind that accompanying all trauma-tism is swelling, due to the congestion or oedema, it will be readily seen why the fatal symptoms accompanying these cases are symptoms of compression. The compression either being due to hemorrhage in or outside of the dura, swelling or oedema, it matters not which, the problem is that of pressure.

It is not the simple linear fractures that kills forty per cent. in the first forty-eight hours, it is pressure. It is pressure that gives the slow pulse, slow respiration, that may possibly be irregular, or even Cheyne Stokes.

It is pressure that gives secondary unconsciousness which may or may not have been preceded by a conscious interval. It is pressure that puts the vital centers out of business and it is pressure that kills the patient.

Consequently the relief of pressure is the entire problem in the treatment, and under no circumstances an ice cap and waiting for development. Von Bergman says after the first forty-eight hours the prognosis in these cases are good for life, though not necessarily for health. It is true that a great many of these fatal cases die in the first forty-eight hours, but oedema kills many more in the second or third forty-eight hour periods. This can be shown by reading over the thousand cases of head injury reported by Phelps, in the *Annals of Surgery*, September, 1909. He has also shown in that report that more than half of the cases that had complete unconsciousness, died, (318 fatal; 224 recover). He further shows the temperature is the most important guide as to prognosis, not a single case in the thousand that showed a primary temperature of 102 recovered.

It is very obvious that if it is pressure that kills the patient, and a great majority of the fatal cases died in the first forty-eight hours, the plain indication, and the only indication, is to relieve the pressure, and to do it quickly.

The best method of doing this is that outlined by Cushing.

Through a split muscle incision opening down to on the middle of the temporal fossa, the removal of a circle of bone 1-2 to 3-4 inches in diameter, the dura is then opened, all necessary exploration can be made and the opening enlarged, if necessary, to tie the middle meningeal.

Drainage is established by tucking a folded piece of rubber dam under the temporal lobe and out the lower end of the incision, particular attention being paid to the secure closing of the fascia of the temporal muscle.

Quoting Cushing, "the advantages of the procedure in addition to its simplicity may be as follows; first, the approach is made through the thinnest available parts of the skull; second, the opening is made under the temporal muscle, the fibres of which are split and not divided, so that when closed they serve to prevent too great bulging, if the tension tends to make the brain herniate, and serves also to prevent a subsequent obtrusive depression when the normal condition has been restored. A subsequent defect in the situation is perfectly harmless; third, in case there has been a rupture of the meningeal or of one of its branches, the extradural clot is certainly brought into view by this opening and as the meningeal trunk is exposed the vessel can be easily ligated; fourth, in all bursting fractures accompanied by laceration of the brain, it is the tips of the temporal and base of the frontal lobes which most frequently suffer, and a subdural extravasation from this source can most readily be dealt with through an opening in this situation; fifth, in a large portion of bursting fractures the line of fracture seek out the mid-cranial fossa, and hence free bleeding from the base can be most easily drained through the temporal fossa by protective drains placed under the temporal lobes; sixth, the subsequent oedema and swelling of the brain, which is an almost invariable sequel of any serious cerebral contusion and which is responsible in many cases for the pressure symptoms during the first two weeks, can be best combated by an opening in this situation in the muscle; seventh, aside from the prompt subsidence of the acute symptoms which are so often seen after these operations, they appear to lessen many of the unpleasant late sequels—traumatic neurases are so often a feature of the cases which have recovered without operation."

Cushing reports fifteen cases with two fatalities both of which he believes were due to not making a decompression on both sides, as post-mortem showed an extradural hemorrhage that could not be easily controlled, and pressure relieved.

This operation can be done with such rapidity, and the scalp heals so rapidly, with so much resistance to infection the patient picks up so little additional risk and his prognosis is so vastly improved, that I believe the operation is indicated in the first twenty-four hours of all bimaxillary fractures, no matter how well they seem to be doing.

Cushing says when in doubt as to the diagnosis, operate, and operate on both sides. I believe he is right in this advice. In other words, you have a case of head injury, unconscious, slow pulse, and possibly irregular breathing, and you are unable to make a diagnosis as to the exact nature of the injury. You do know, however, that you have pressure, and the plain indication is to relieve that pressure if you can, and to do it in the first twenty-four hours.

I will report five of my own cases.

Case 1. J. R., white, age 19. First seen by me afternoon of March 30, 1909, gave a history of having fallen from a telephone pole about 25 feet to the ground, showed a bruise and an excoriation over the lower lip and chin running up the left side of the face, and over the left eye, extending well beyond the middle of the forehead.

The left eye was swollen shut, seventh and eighth ribs fractured at the posterior axillary line, abdomen hard, retracted and rigid. His mental condition was confused, sleeping heavily a greater part of the time, but could be readily aroused. A depression was considered, but postponed on account of the rather severe shock and evidence of internal injury, as evidenced by his passing bloody urine and by his vomiting a large quantity of blood. Later he rallied from the shock, and about the third day began to complain of a severe pain in the right ear, a paracentesis was done, which evacuated a considerable quantity of bloody serum, he was purged with calomel and salts and his condition improved, he laughed and talked and asked for and received light nourishment.

At nine o'clock on the seventh day after the injury, he complained of a severe headache and died five hours after the beginning of this headache. His pressure apparently being due to the oedema of the brain.

During the first twenty-four hours of this man's injury I was kept from decompressing him on account of his severe shock and abdominal injuries. After the first forty-eight hours his condition improved so rapidly that I did not have the nerve to advise a decompression, though I have wished many times since that I had. I believe firmly had he have been decompressed he would not have died.

Case 2. R. F., white, age about 30. Diagnosis: Fracture of the left temporal bone. History: On May 25th or 26th, 1909, while

under the influence of alcohol, received a blow over the left frontal from a monkey wrench in the hands of a drunken companion. Gave a history of having had a conscious interval. Seen by me May 27th, profoundly unconscious, snoring loudly. Operation: Through a split muscle incision, the temporal fossa was opened, and a large blood clot was found and removed, and the middle meningeal artery was tied. The artery was ruptured by a linear fracture running from well up toward the vault, through the temporal bone and into the middle fossa.

Patient left the table in good condition, did not regain consciousness, and died the next day. Post-mortem showed a repetition of Cushing's two fatal cases. A large extradural clot with a linear fracture, and rupture of the middle meningeal on the opposite side, in every way duplicating the injured side, on which the blow was received. Had this man been decompressed on both sides he would have lived.

Case 3. Mike Benton, white, age 23. August 16, 1910, injured by a slate roof in a coal mine falling on his head, face smashed against the floor, both eyes closed. Cut beneath the right eye and scalp over occiput one inch long. Hematoma over right parietal, right temporal and facial regions very much swollen. Nose and mouth full of dried blood, stupid mentally, though conscious, no history of unconsciousness.

August 18th stupor deepened to the point of coma (Tyros) showed blood pressure systolic 125, pulse and respiration becoming more slow.

Operation: Circular incision, flap turned down in order to expose the large hematoma over the right parietal under which was found a clean cut through the bone about 1 inch long and one-half inch in width, out of which was oozing blood and serum, in other words his accident had decompressed him to the extent allowed by the scalp, this accounted for his alarming symptoms coming on as late as the night of the third day. The opening of the bone was enlarged, extending down under the temporal muscle 2 1-2 inches long, dura opened and serum spurted out showing considerable pressure.

Two strips of rubber glove used as a drainage coming out through a stab wound in the temporal muscle, the wound closed with a silkworm gut. In twelve hours he showed considerable improvement, which gradually progressed to complete recovery; left the hospital on the tenth day against my advice, with a small granulating spot at the site of drainage and a pulsating area about the size of a dollar.

Case 4. H. G., male, white, age 18. Diagnosis: Fracture of the base. On the night

of September 5, 1911, was in an automobile accident. Physical examination showed next morning, bleeding from the left ear, a small hematoma over the left mastoid process. A facial paralysis of the left side, a fractured clavicle middle third, a very large laceration and some denuding of the skin over and above the left ilium.

He came out of his unconscious state in the forenoon on September 6, recognized friends and answered questions intelligently. At three o'clock in the afternoon on the same day his unconscious state returned, being more profound; at this time it was impossible to arouse him by shouting to him accompanied by sharp slaps on the cheek. Operation was advised and proceeded with after the manner of Cushing's both sides. Drainage was satisfactory, complete consciousness had returned in forty-eight hours. Convalescence was uneventful. Facial paralysis, evidently caused by the injury to the nerve in the aqueductus fallopii, was uninfluenced. Recovery was complete, after four months facial paralysis had almost completely disappeared.

Case 5. M. M., white, age 18. Diagnosis: Fracture of the base. History: October 8, 1911, jumped from a buggy in a runaway accident, landing on the left lower occipital region, picked up unconscious, brought to me the same day.

Physical examination showed a severe laceration without break in the skin, behind the left ear profuse bleeding from the left ear, from the nose and posterior pharynx, profoundly unconscious, pulse sixty, snoring loudly. Decompression both sides the same morning. Drainage satisfactory, though more on the left side than on the right. After third day had voluntary intervals of complete consciousness, these intervals increasing in length up to the tenth day at which time she had returned to normal. The drains were removed at the end of seventy-two hours and primary union was complete. Is entirely well and has since married.

To recapitulate: The advice to operate practically on all recent fractures, is the extreme of radicalism and is warranted by the facts.

The open treatment of fracture is difficult work, requires a well-developed technique, and team work between the operator and the assistant.

Under favorable conditions the open treatment should be advised as soon as it becomes very doubtful that a functional result will not be had by splints.

Certain fractures of themselves demand the open treatment, depressed fractures of the base, and fractures of the patella.

It is not good surgery to plate many compound fractures, and remove the plates as

soon as a good position is assured.

It is pressure from swelling, hemorrhage, or oedema, that kills the patient in the simple linear fractures of the base.

Decompression is the only indication, and should be done early, (in the first twenty-four hours). Decompression vastly improves the prognosis, and picks up very slight additional risk.

If decompression is done at all, do the operation on both sides, it can be done on both sides in about thirty minutes, or less time.

TOXIC INSANITIES.

By MURTON BOARD, Louisville.

The classification of mental diseases continues to multiply as rapidly as text books upon psychiatry are produced, each author finding fault with the existing classification, for faulty indeed they are, and each thinks himself capable of improving same—a most difficult task.

Krepelin has done much to bring order out of chaos in showing that certain mental symptoms are manifest at one stage of a psychosis and certain other symptoms at a different stage in the same individual, his classification, however, or the lack of it, is confusing to any except a mind that delves deeply into the subject matter, the average student or practitioner demanding a simpler arrangement. The Medico Psychological Association, of Great Britain, has adopted a classification which is in general use in that country. It is remarkable for its clearness and simplicity. Our country being made up of so many states no such general classification has been adopted, although an attempt was made in 1886 by American alienists to bring about some uniformity by the adoption of the English classification with the exception of the form "Moral Insanity" and the addition of the form "toxic insanity." The English classification is as follows:

1. Congenital or infantile mental deficiency
 - (a) With epilepsy.
 - (b) Without epilepsy.
2. Epilepsy (acquired).
3. General paralysis of the insane. (Paralysis).
4. Mania—recurrent, chronic, recent, a parturient, puerperal, senile.
5. Melancholia—recent, recurrent, puerperal, senile.
6. Dementia—primary, secondary, senile, organic.
7. Delusional insanity.
8. Moral insanity.

Notwithstanding this or any other classification, however, mental manifestations con-

time to appear in individuals refusing to be grouped or to remain classified. This has ever been and will so remain so long as the pathology of mental diseases remains obscure.

Mr. A., a young mechanic, is admitted into a Psychopathic Hospital, he is restless, excited, has not slept for a week except as a result of hypnotics administered in heroic doses, he has delusions of various types, talks at random, with more or less incoherence, his memory is perfect, his tongue looks like a bath towel, his bowels are costive. He is treated by active elimination, he is separated from his home and business environments for a period of some six or eight weeks and recovers. A recurrence is apt to appear in one or five or twenty years, but may never appear. He marries, has a family and leads a comparatively useful life.

Mr. B., a young bookkeeper, is admitted to the same hospital in the same week. He manifests practically the same symptoms, he is given the same treatment by the same doctor, handled by the same nurse, yet after passing through the stage of excitement and becoming quiescent, his delusions continue, become fixed. He is classified as a paranoiac and eventually becomes demented.

Why the difference in the outcome of the two cases? Because of the difference in the pathology but what that pathology is in either case is difficult to determine. We only know as clinicians that what happened in these two cases is going on all the time in every institution where the insane are treated in the land.

Toxic insanities are a most interesting group of psychic disorders because they are the most curable in a number of instances. I shall divide them into two groups:

1. General Paresis.
2. Confusional Insanity.

The latter will be sub-divided when we come to treat of it after we have directed our attention to the first type.

GENERAL PARESIS.

Paresis is a form of insanity in which there is a mental disorder of several types accompanied by progressive paralysis. It is a disease of the brain and spinal cord usually characterized by maniacal symptoms in the early stage followed by mental failure and physical helplessness. Paresis has been called by Krafft-Ebing a disease of syphilization. It was extremely rare a century ago though probably more cases existed than were noticed. I have never seen a case where a history of syphilis did not exist, though its association with chronic alcoholism is so common as to lead to an opinion that alcohol may produce the disease in a neurotic individual. It is quite common among people of civilization, being most common in Europe and

America. It is rare in Africa and Asia but is quite common among the American negroes. While it is a toxic insanity in that it is due to syphilis and at least aggravated by excessive alcoholic indulgence, yet it is degenerative also, that is, it has its origin in a neuro-pathic constitution as indeed have most mental diseases. It is more common in men than women in the proportion of five to one, though the disease is becoming more common in women. Mental strain, excesses of all kinds act as predisposing causes, but the consensus of opinion is that two elements are essential to the existence of the disease, namely, the neurotic condition and syphilis.

SYMPTOMS.

The disease can be divided into two or three stages,

1. A period of incubation, which is not a true stage,
2. A stage of maniacal activity,
3. A stage of mental enfeeblement and physical helplessness.

Sometimes, however, the prodromal stage is insidiously followed by a period of depression or melancholia from which the patient passes into a stage of mental and physical helplessness without any, or very little, excitement. As a rule, however, a period of excitement exists which is sometimes very violent. A diagnosis is generally made at this time. In a typical case a period of irritability with a patient easy to fatigue together with forgetfulness ensues, this is followed by a stage of excitement in which a man formerly retired and cautious becomes talkative and indulges in excessive speculation, feels fine, cannot be controlled, imagines he is rich and has great schemes for enriching others. After confinement in an institution for a time the excitement subsides and the patient seems almost normal but in a few months signs of dementia appears, memory becomes weak, speech and writing incoherent, pupils react badly to light, knee jerks are frequently abolished. In the second stage some of the symptoms of the period of excitement may remain, but they flicker as a candle. The disposition to fight when opposed is ever present until a condition of general helplessness ensues. Finally complete prostration is present, the patient has to be cared for like a child. Death results from exhaustion frequently preceded by convulsions. The latter may appear at a earlier period of the disease and may be epileptic in character.

DIAGNOSIS.

Several types of paresis existing the diagnosis is not always easy, besides cases of syphilitic pseudo paresis and alcoholic pseudo

paresis are described, both these conditions yield to treatment.

With a history of syphilis, facial and tongue tremor, irregular pupils and knee jerks, disturbance of speech, weakness of memory, not much inclination to work, irritability, change in hand writing and a general lowering of moral idens, the diagnosis may be made early, in the latter stages the diagnosis is easy.

PATHOLOGY.

The disease being due to syphilis, syphilitic lesions will be shown in the brain and cord. Thickening of the membranes and vessels with cell degeneration. The dura is thickened, the brain itself atrophies, the cerebro-spinal fluid is increased, the other membranes of the brain are thickened.

PROGNOSIS.

The prognosis is invariably bad, though improvement will appear after the stage of excitement in most cases. The disease terminates in from two to five years.

TREATMENT.

A quiet life in an institution is indicated in the early stages, anti-syphilitic treatment is generally given but is of little value in true paresis. As the disease progresses confinement and proper care are about all that can be done.

CONFUSIONAL INSANITY.

Dana divides the different types of Confusional Insanity into three groups:

1. Exhaustive psychoses,
 - (a) Collapse delirium,
 - (b) Acute dementia, primary dementia, dementia, acquired dementia.
2. Infection Psychoses,
 - (a) Febrile delirium,
 - (b) Multiple neuritic psychosis.
3. Toxic Psychoses,
 - (a) Alcoholic insanities,
 - (b) Drug insanities,
 - (c) Auto toxic insanities including thyroid and myxoedematous.

In this field the psychiatrist does his greatest good and makes his reputation for most of these types respond rapidly to treatment and in the course of a few weeks or months at most, recovery takes place. I have not time in a paper like this to go deeply into these different types, but will say that if the profession will learn to recognize these cases, or, if doubt exists, as it often will, give the patient the benefit, give him a month or two of individual attention, recovery will generally take place and the stigma of asylum commitment be avoided.

The patient in these cases suffer from some form of infection. It may be pneumonia, la

grippe, typhoid fever, puerperal sepsis, long continued alcoholic indulgence or the irregular use of morphine or cocaine. As the febrile state subsides the mental symptoms appear. It may assume the form of acute delirium, hallucinations and delusions appear, sometimes the patient is dull, sometimes noticeably excited. After a few days, at times, generally a few weeks, often several months, the excitement subsides, the delusions disappear, but for some time the patient is dull, memory weak with depression a chief symptom. Occasionally, recovery does not take place, a state of chronic apathy or depression exists throughout the remainder of the patient's life. As a rule, however, as I stated before, recovery ensues.

TREATMENT.

Hydrotherapy ranks first, hot and cold water properly applied is worth everything else that we do, elimination by the bowels and kidneys ranks second. Sedatives other than preparations of opium, which should not be used at all, rank third. Other treatment is symptomatic. Proper feeding is highly important as death can result from exhaustion and the heart must be closely watched.

The field is intensely interesting because tangible speedy results are obtained. I would call attention briefly in closing to two conditions mentioned in the group of toxic psychoses because of their immense importance. I refer to morphinism and alcoholism about which much is written and about which the voice of the charlatan is "heard in the land." I shall discuss them in the order named.

I.—MORPHINISM.

Morphinism is a psychosis. Every habitual user of the juice of the poppy is insane and ought to be so considered. I go further and declare that every confirmed morphinist ought to be confined, under the statutory laws of the state, in an institution where they will be properly treated, in many instances restored to society which will be protected from their baneful influence and example.

The number of drug users is increasing to an alarming degree. One morphinist frequently occasions another, as witness the husbands and wives addicted. This condition frequently grounded in a constitutional neurosis is not a habit, is not a criminal propensity, though it may be associated with it. It is a disease—a deep-seated one and cannot be easily eradicated. Earlelmyer, perhaps the greatest authority on the subject, says that the prognosis is absolutely bad. He is not far wrong for it is certain that months of treatment and years of watchfulness are required to save an individual once a chronic victim of morphine. It is not necessary to

stop to condemn the various quack institutions and cures which have sprung up all over the country, purporting to give rapid and painless cures to these victims in the past quarter of a century. They have not all combined cured one chronic morphinist. That the laity would be caught by the alluring advertisements of these quacks is not surprising, but that members of the medical profession would be duped thereby, is appalling. Whatever is done in the management and treatment of these unfortunates that is really good will be accomplished by the ethical scientific members of the profession, men like Crothers, of Hartford, who are willing to devote their lives to the study of this great question.

ALCOHOLIC INSANITY.

Toxic insanities due to alcohol differ but slightly from other confusional types responding rapidly to the same care and treatment and generally ending in a few days or weeks in recovery. Delirium tremens requires careful nursing and close watchfulness on the part of the physician, as death from heart failure is apt to occur. The chronic alcoholic is very little different from the morphinist, frequently a neurotic individual to begin with he succumbs rapidly to social influences and soon reaches the point where a true psychosis begins. Here again the so-called quack cures are a failure. A few days or a few weeks spent in getting sober is merely of temporary benefit. The condition is probably curable in many instances, but months are required and a complete change of environment essential to a cure that gives any reasonable promise of permanency.

ECLAMPSIA.*

By EDWARD WILSON, Pineville.

Eclampsia is one of the most alarming, as well as one of the most dangerous conditions with which the general practitioner has to deal. It occurs about once in every three hundred cases of labor. Its mortality varies from 33 to 67 per cent. in different hospitals and in the hands of different physicians.

The causes of eclampsia are first, the excessive nervous irritability of pregnancy; second, the retention in the system of urea, also anything which causes pain or discomfort, such as distended bladder or labor pain.

The treatment of eclampsia is the use of remedies to relieve the causes, the greatest of which is morphine, it controls the nervous irritability and relieves pain; second, is purgation, warmth to the surface, and usually forcible delivery, my cases of eclampsia are as follows:

First. Patient eighteen, married at fourteen, convulsions at full term, gave her half grain of morphine hypodermatically, did a forcible dilatation, delivery by forceps under chloroform, patient and baby both lived.

Second. Patient seventeen, married, sister to first case, five months pregnant, gave her half grain morphine hypodermatically, examination showed cervix not obliterated, put her in a warm bed, gave saturated solution of epsom salts, every half hour till bowels moved, convulsions stopped, gave her calomel, four grains every week, salts every day, diet limited to milk and crackers, at the end of six weeks albumen suddenly decreased, two weeks later she was delivered of a dead foetus by Dr. L. D. Hoskins. She still lives. The father of the two women died of Bright's disease.

Third. Three convulsions, great deal of anasarca, weak pulse, undertook to deliver her, she died in the operation under chloroform. Did not give her any morphine.

My idea is the treatment suggested above, with forcible delivery after seven and a half months' pregnancy, or before if cervix is obliterated, or os dilated.

ALCOHOLISM.*

By T. T. GIBSON, Middlesboro.

By alcoholism, we understand a series of morbid phenomena that are directly due to the toxic effects which result from the excessive and prolonged ingestion of alcohol, which may be divided into three stages; viz.: Acute alcoholism, or drunkenness; (2) Acute alcoholic delirium, or delirium tremens; (3) Chronic alcoholism, habitual drunkenness, or inebriety. The last division of which I will attempt to discuss in this paper.

ETIOLOGY.

A great per cent. of the inebriety of our country is derived from good fellowship and sociability which leads the weak-minded and ignorant to continuously overload their system with intoxicating beverages. Other causes are worry, anxiety, insomnia, disappointment, and domestic unhappiness, and many other conditions which induce the individual to seek relief in alcoholic beverages. The man takes the first drink; the first drink takes a second, the second, a third, and so on, until the system absorbs so much alcohol that it is beyond his power to resist the temptation of a drink—the alcohol in his system calling for more alcohol—thus we call him an inebriate, a chronic drinker or nervous wreck.

The influence of heredity upon alcoholism is a very interesting question. In my opinion it is as impossible for a child born of an inebriate mother or father to inherit an uncon-

*Read before the Bell County Medical Society.

*Read before the Bell County Medical Society.

trollable desire for alcohol as it is for a child born of a morphine habitue to inherit an uncontrollable desire for morphine, however, it is true that the child born of an alcoholic mother or father may inherit an unstable nervous system—one that does not maintain its normal equilibrium—that responds unduly to the ordinary wear and tear of existence—that does not possess sufficient vitality to give to the body the tone and vigor that is required in the ordinary performance of body functions. With this defective condition throughout the central nervous system, this lack of normal equilibrium, it is perfectly possible that the child, in the environment in which it is likely to live, may become addicted to the use of the alcohol or anything else that is equally available.

MANAGEMENT.

In the management of inebriates, we have to deal with different classes: Those who drift into chronic alcoholism unintentionally and without any definite purpose in view, and who come to a physician for help with evidence of a fixed determination that they want to get rid of their disease, can usually be handled with good success outside of an institution. Others without character, drifting selfishly through the world, without rudder, compass or objective point are, almost without exception, hopeless outside of an institution and often hopeless even in an institution. Private institutions often obtain splendid and lasting results, but in the majority of cases patient cannot be kept for a sufficient time in order to prevent subsequent relapses. State institutions for inebriates is a matter which has been sadly neglected by not only our own Commonwealth but by the majority of the states in the union. The expense of such an institution, with proper provision for the care and treatment of inebriates, would be more than saved within a few years, by a lessening of the number of unfortunates who to-day overcrowd our jails, work-houses, penitentiaries, insane and other asylums. The saving to such unfortunate families and to future generations, would more than justify such expenditure.

TREATMENT.

In treating these cases, we have no state institution to take care of them and the vast majority of them are financially unable to attend a private institution. Under such conditions, the medical profession should awaken to the importance of cause and effect and cognizant of the obligation that we owe our fellow-men, should strive to bring the matter of a state institution before those at the helm of our State.

In the medicinal treatment of these cases, I absolutely discontinue alcohol at once, giv-

ing them plenty of good nourishing food and sleep, being careful not to overtax the nervous system. In my opinion, free elimination of the poison from the system is a very important factor. For this purpose, I have used compound cathartic pills, one every three hours until five have been taken, followed with tincture of belladonna and fluid extract of xanthoxylum with an increased dose, repeating the fourth day four of the pills, one every three hours, following again with the belladonna and xanthoxylum, then a round of the pills once a week for several weeks, then every two weeks, then gradually leaving them off, not forgetting the important fact of encouraging your patient with kind words and good moral lectures, explaining to him that this treatment will remove from him that uncontrollable desire for alcohol; that he himself must be a man morally and fight for himself against the good fellowship and sociable drinks, lest he satiate his system and be overcome again with that uncontrollable desire for the same poison.

HOOK WORM DISEASE.*

By B. E. GLANNINI, Straight Creek.

Hookworm disease is a disease found especially in warm weather, it is due to certain species of hookworm, the ankylostoma duodenale, old world hookworm, sometimes called "meimaria duodenalis" and "nector Americanus," new world hookworm. Warm mines and damp earth offer favorable conditions for hookworm disease, people who come in contact with water containing larvae of the parasites are easily infected. The disease is recognized by the discharge of the ova of the worms with the feces by a progressive anemia, general weakness, impaired development in young subjects, also digestive, nervous and circulatory symptoms. We have what is known as the hookworm carrier, a term applied to persons in whom hook worms live as parasites, but who either from small number of worms, from race immunity, or from other causes do not develop obvious symptoms.

HISTORY.

The history of hookworm disease is identical, as we now know, with that of cases described in various tropical countries, during three centuries, viz.: Pise, in Brazil, (1648); Father Laba, in Guadeloupe (1748); Bryon Edwards, in Jamaica (1799); under various names given in the list of symptoms, viz.: anechilosomanemia (Italian) ankylossomen (German); Egyptian or tropical chlorosis, tunnel-maker's anemia, tunnel disease, brick-makers' disease, mountain anechlexia, mountain

*Read before the Bell County Medical Society.

anemia, miners' anemia, miners' cachexia, negro consumption, the yellows.

The synonyms of hookworm disease indicate the wide range of symptoms and the extensive geographic distribution as shown by the diversity of languages.

In the early centuries hookworm disease was not truly understood and often wholly misinterpreted, and this continued up to a recent period, the discovery of the first hookworm had little, or no, influence on clinical study. Certain disease described by older writers can also be explained now by hookworm disease. Anemia was striking symptom, and the epidemics of miners' anemia in 1786, in Hungary, where more than 1200 miners were affected, there were similar epidemics between 1802 and 1820, in the mines of France, Hungary and Bohemia. Hammerschmid noted that the disease differed from ordinary anemia, or chlorosis, that it represented a disease and that the explanation by the mine climate, or vitiated air, was not satisfactory.

In 1838 Dubini, an Italian physician of Milan, first described hookworm disease; since then many other observers all over the world have described the disease and added a great deal to Dr. Dubini's discovery. Dr. Stiles quotes Joseph Pitt, 1808, as the earliest author he has found to refer to the disease in this country. Pitt described dirt-eating among poor white people and negro slaves, and thought it was due to lack of nonrish-bent. But it remained for Dr. Stiles, himself, to make a thorough research, which resulted in his discovering that the entire South was infected with hookworm disease.

Dr. Stiles found his first hook worms in Virginia after which he made extensive investigations throughout the entire South, gathering all the information he could and adding his own personal work to it. Dr. Stiles' timely investigation of hookworm disease opened up a new field of work, that is today being investigated and treated all over the South, and I may say, cured.

HOOKWORM DISEASE IN KENTUCKY.

In the fall of 1910, the Surgeon General of the Army gave out the information that recruits from Kentucky were infected, after that Dr. L. H. South started a systematic investigation and she is now able to show that hookworm disease exists in fifty-five counties in Kentucky, and that the mountains of Kentucky are heavily infected. Dr. South is covering the ground thoroughly in Kentucky, and it is our duty as physicians to cooperate with our State Board of Health, in this fight against the hookworm or the "American murderer." In Kentucky it has been shown that the infection is much greater in whites than

in the negro. Some of our wealthiest and best educated people have been found to be infected with hookworm disease.

CAUSES.

We find two kinds of hookworm, the new world form called "Necator Americus." (Dr. Stiles named the new world hookworm the "American Murderer.") The old world form is called the "Achylostoma Duodenale." The new world hook worms are slender worms varying in color from a dead white to a dirty gray and sometimes slightly red. From ingested food the worms are about one-half inch long, and about as thick as an ordinary hair-pin, of course varying according to their age. The worms inhabit the bowels and are sometimes found in the stomach. The new world hookworm, as described by Dr. Allen J. Smith, is provided with a "dorsal conical-shaped tooth" in the median line and the upper or buccal cavity of its head contains the ventral lancets, which are not exposed; the lower lancets are small and conical, with the tooth in the median line and with his strong jaws he is able to attach himself to the mucous membrane of the bowel; the lesions produced by the attachment of the worms are usually a dark red or slate-colored pigmentation, the lesions are usually the same level as the surrounding tissues, yet they may be nodular in character. In the midst of the red area is a small pale elevation at the summit of which the worm may be seen adhering, or the hole caused by its bite after the worm has fallen away. The worms suck the blood, and produce a poison which is very injurious to the person affected, and this poison is believed by some observers to be largely responsible for the anemia found in these cases. The quality of the blood is reduced by the poison, digestion and assimilation is impaired and a general physical and mental weakness follows, which in turn predisposes to other diseases and a lack of development in young subjects. The general disregard for sanitation in small towns and in the country, plays an important part in the causation of hookworm disease. With the general disregard for good sanitation and the open privy, and the cats, dogs, hogs and chickens eating the feces of hookworm subjects and in turn scattering their droppings around over the premises and farms, you can readily see how the hook worms ova are scattered from these unsanitary privies, and it has been proven that hook worms do not hatch in the bowel.

MODES OF INFECTION.

The most frequent mode of infection is through the skin. Dr. Loose, in 1898, proved this by experiments and accidentally infected himself while experimenting with the larvae. The larvae penetrate the skin in a

very short time; and with remarkable power they plough through the tissues. They continue to penetrate the tissues until they reach the capillary blood vessels, once in the blood stream they are carried to the right heart, from the heart they are carried by the blood stream to the lungs. Here they are caught in the capillaries, because they are so much larger than the smallest capillaries of the lungs and can not pass through. Meeting with obstruction they again penetrate the tissues and soon are into the bronchial tubes. After the larvae reach the bronchi they are carried to the mouth either as a result of the normal, constant, outward current of bronchial and tracheal mucus, or by coughing. No doubt many of them are spit out, but some are swallowed, according to whether the individual spits out what he coughs up or not, of course habits vary a great deal in this regard, as is well known, and this is an important factor in determining the extent of infection, and in view of this it seems wise to advise patients with "ground itch" not to swallow any sputum at all. Another mode of infection is food that has been contaminated with infected mud or water, or that has been infected by persons handling the foods that are infected. Vegetables, such as lettuce, celery, and strawberries, and others that are eaten raw. In this way the larvae are swallowed and are carried into the stomach and bowels. Drinking water may become a source of infection, but the probability of getting any considerable number of the larvae in this way are very remote and is given very little attention. Experiments by Bass and others show that the daily stool of a patient infected with an average number of worms will pass anywhere from 1,000,000 to 4,000,000 eggs daily. In the light of these figures the wonder is that the disease is not far more destructive of human life than it is.

SYMPTOMATOLOGY.

In considering the symptoms of hookworm disease we have three classes of cases to consider; namely, slight cases, moderate cases, and marked cases, and we will find the symptoms vary according to the severity of the infection, and the general condition of the patient. Some patients are more able to resist the disease than others. The first class of cases, or the slight cases, present very few symptoms at all. You will usually find a little pallor of the skin, or a slightly yellow tinge of the skin, a reduction of perspiration. The appetite may be very slight or in some instances ravenous. A little uneasiness is usually felt in the epigastrium, and an occasional attack of gastralgia, at odd times a slight breathlessness, on exertion, occasional palpitation of the heart, dizziness, headaches, lack of

attention to details, and a little dulling of the mental faculties. Some cases show a slight flabbiness of the muscles and weakness and an indisposition for labor exists. The hemoglobin of such persons generally lies between sixty per cent, and normal.

MODERATE CASES.

In moderate forms all of the symptoms noted in the slight forms are more prominent, the pallor being definite, dry skin, sweating is rare; appetite may be exaggerated to the point of bulimia, or it may be just the reverse. Often tenderness of the abdomen and epigastrium and oftentimes a sensation of heaviness. Breathlessness, palpitation of the heart is frequent, pulse more rapid, may be weak and compressible, pulsation of the neck is often marked. Often pain in the sternum and chest, and a feeling of weakness in the knees and legs. If the infection occurs in the young a lack of development of the child is noticed, both physically and mentally. In the early stages of the disease "ground itch, toe itch, or what is commonly termed dew itch or poison, is found upon the feet and ankles and nearly all cases give a history of having had some of these troubles. The face may have an anxious expression, or one of stupidity. The patient complains of dizziness, nausea, headache and noise in the ears. The mental condition is depressed and the patient appears stupid, the patella reflex is usually diminished, but may be exaggerated, the feet tingle and often "go to sleep," the muscles are flabby, and often painful, joint pains are common, and may lead you to suspect rheumatism, work is undertaken with great effort. Hemoglobin is apt to be between 30 and 60 per cent.

MARKED CASES.

In this class of cases we find that pallor is in the extreme, edema of feet and ankles, and sometimes extreme anasarca. The patient may have no desire for food at all and again it may be next to impossible to satisfy the patient. The fact that these patients have a desire to eat abnormal articles of food, is why these poor unfortunates are termed dirt-eaters, many of them will eat flour, ashes, pepper, salt, chalk, decayed wood, charcoal, mortar and plaster, paper, cloth, tobacco, dirt and clay, sour pickles, lemons or anything sour. Heartburn is a common symptom and it is claimed by some observers that many of these patients get in the habit of eating these things to relieve the heartburn and the pain in the epigastrium. Nausea and vomiting are frequent. Ascitis is liable to appear. Diarrhea or constipation may be present, dyspnea, on slight exertion, and often when patient is quiet, severe palpitation of heart, precordial pains, rapid, weak compressible pulse, and of-

ten dilatation of the heart, marked pulsation of the blood vessels of the neck, impotence in men and amenorrhoea in women, intellect dull, patient seems confused and stupid, the facial expression is of melancholia and anxious, the urine has a low specific gravity, is abundant in quantity, usually no albumin, extreme weakness and the patient has arrived at a stage where the case may have a fatal termination at any time.

DIAGNOSIS.

To make your diagnosis clear it is necessary that you find hookworm eggs in the feces of your patient. While you may find many cases with symptoms that will lead you to a diagnosis of hookworm disease, a history of having had ground itch, or toe itch, and the patient presenting the pallor and anemia with lack of development, palpitation of the heart, indigestion and a feeling of uneasiness in the abdomen should lead you to suspect hookworm disease and make repeated examinations of the feces, which, of course, will clear up all doubt and make a diagnosis certain. In making your diagnosis, however, it is well to have in mind pellagra in its incipient form, as some of these pellagra patients will present a general weakness together with the tired feeling and anemia and indigestion before there is any eruption at all. One patient I have in mind complained that he had no desire for water and had an increased flow of saliva, also suffered from insomnia for several weeks before the eruption appeared on his hands, and in this connection I wish to state that after observing several cases of pellagra in which I found hookworm disease, it occurs to me that hook worms, in some remote way, may be a factor in the etiology of pellagra, either by the general weakened condition of the patient and the anemia, or the irritated condition of the bowel, produced by the worms or by the absorption of the toxic substances generated by the worms themselves.

TREATMENT.

In considering the treatment of hookworm disease it is well to consider the treatment of ground itch and toe itch; although it is not often that patients consult doctors with toe itch unless it is in mining camps. They usually apply some patent salve or home remedy, but we, as physicians, should teach the laity the importance of this trouble and advise them in regards to spitting out all sputum after having had toe itch, or ground itch, vesicles on the feet should be opened freely and washed with a carbolic acid solution about 1 to 40. The ulcers will leave in about eight to ten

days in most cases. A good salve to use is R.

Carbolized Salve 1-2 ounce
Zinc Oxide, Ointment 1-2 ounce
Balsam Peru 1-2 dram

Mix. Apply locally twice daily, also bathe the feet in hot water, it seems to hasten healing and keep the feet bandaged.

Several remedies are used to expel the worms. Thymol is most generally used in America and England. The dose of thymol given should vary, of course, according to the age and condition of the patient. Drs. Ashford and Kings' dose table is a good rule to follow although I have gotten good results from smaller doses. This table is as follows:

Under 5 years old in size	 7 1-2 grains
Five to 10 years old in size	 15 grains
10 to 15 years old in size	 30 grains
15 to 20 years old in size	 45 grains
20 to 60 years old	 60 grains
Over 60 years old	 30 to 45 grains

Unfavorable conditions such as extreme anemia, pregnancy, great weakness, cardiac depression, and diarrhea may require still smaller doses. The doctor should be the judge. The most convenient time to take the treatment is on Saturday and Sunday. Dr. Nuckols and myself have had about one hundred cases at Straight Creek, and our plan of treatment has given us good results. We give on Saturday 5 grains of ammonia chloride, every two hours, until 30 grains are given. At bedtime 5 heaping teaspoonfuls of Epsom salts and withholding all food and only allowing our patient a cup of coffee without cream if very hungry.

On Sunday,

At 7 A. M., we give 10 grains thymol
At 8 A. M., we give 10 grains thymol
At 9 A. M., we give 10 grains thymol
At 11 A. M., give 4 teaspoonfuls Epsom salts.

Keep our patient in bed, on right side, with hold all food and allow very little water. After 5 o'clock patient can get up, eat and drink as they please. I believe tonics, such as iron, arsenic and strychnia, are indicated in these cases. But even after you have given a treatment of thymol and gotten good results, an examination of the patient's feces should be made from time to time. You may not have gotten all of the worms or your patient may have a second infection.

Iodin in Exanthematous Typhus.—Uffengaufer reports fourteen cases which added to Jaworsky's forty-one brings to fifty-five the number of exanthematous typhus patients treated with tincture of iodine internally, three or four drops three or four times a day, taken in red wine. The disease was unmistakably modified by the medication and evidently much for the better in the entire group, he says.

PROPHYLAXIS OF SPECIFIC DISEASES BY LEGISLATION.*

By T. L. LAMPKIN, Bardwell.

As your retiring president, I have selected this subject to give you a few moments thought of the worst plague that human flesh is heir to, and one that should have our most ardent consideration.

This is not a pleasant topic for discussion, but it is infinitely better to discuss it freely than to permit unfortunate and helpless children and women to be tortured by such horrible diseases. It will be difficult, however, to convince the American people that it is not an infringement of personal liberty or a violation of the Constitution of the United States for medical men and boards of health to compel the people who have not the knowledge of the danger and the contagion of these loathsome diseases, to keep their children clean and pure, and to prevent them from spreading these diseases among others.

Gentlemen of the society, the question of venereal diseases is of great moment in this country, and especially in army and navy. The time lost to the military service by sufferers with this class of diseases is far greater than from any other one disease. The world and the medical men of this country are opening their eyes to the ravages of these diseases now, more than ever they did in any previous history of any disease.

We will not discuss the pathology here, as you all are acquainted with the two diseases, and to enter into a lengthy description of them would consume too much of your valuable time, knowing that every doctor knows what the specific diseases are. You all know the danger of the infection, the susceptibility to its contagion, the dreadfulness of its results to public health, and the sufferings and deaths we encounter each year. Nature has been prodigal in her gifts to our nation. In no respect has she been kinder than in opportunities for health and efficiency. Her very proclivity has rendered us careless and extravagant. It is high time that physicians and Americans do as well for themselves in health protection at home as they have done for themselves and others in Cuba and the Philippines.

This demands the creation and maintenance of official organizations. We should help to extend and replace the work of our organizations, whose lack of authority prevents complete success.

In 1912 there will meet in Washington by the invitation of the President and the Con-

gress of the United States, the International Congress of Hygiene and Demography. This congress meets triennially in the Capitals of the world and brings together the leaders in health conservation.

If they do as before, they will put all their massive minds to work on the prevention of measles, diphtheria, typhoid, scarlatina, smallpox and the plague. Yet, not one word has ever yet been raised against the worst infectious diseases, the worst plague the world knows anything about, viz.: the specific diseases.

There has been much written on the prevention of certain diseases of the South, such as smallpox, yellow fever, and such like, that never affect the North. Climate has largely to do with many of our infectious diseases, by gonorrhea and syphilis are two diseases that climate does not affect. The North, South, East, West, and in fact the whole world is subject to them, and, by the way, we have it sattered all over this wide, wide world. Nearly every person who has arrived at the years of responsibility knows something of these dreaded diseases in every land and country of the universe. Why not we, as medical men of this grand and glorious country, be the first to start a campaign of warfare to have these two dreaded diseases quarantined as all other infectious diseases?

The medical journals are full of literature on prophylaxis of venereal diseases, but, if you notice they all are recommending some drug that will cure the disease. When we got "606" into circulation, we thought the Jesus of remedies had arrived, and we could pollute ourselves to any excess, and to the vilest cases, without the least doubt of infection when we applied the divine "606". But alas, after a while, came the reports to bring the sad news to us that "606" is dangerous, it is uncertain, and there are many complications, and in the true fact of experience, it is not any more safe than the old-time forms of mercury.

Now, what are we to do? Only sail back to our old sea of trouble and danger. When the claims for "606" were being widely heralded through the daily press, I was amused and disgusted at the attitude of certain well-meaning people, and some doctors, who spoke of the new discovery for syphilis. They thought it was a positive and deadly menace to the mortality of the country; that the victim of syphilis now had a positive cure, and no fear to keep him in the narrow road of chastity, he could roam the sexual fields the balance of his life, and if "caught" could get immediate relief. Such thoughts are only evidence of the deepest and most dangerous ignorance, for the principal suffering from venereal infection is not the original sinner, but the in-

*Read before the Carlisle County Medical Society, Bardwell, and the Southwestern Kentucky Medical Society, Paducah.

nocent wives and children, there is the rub?

Now they have "606", or Salvarsan, reaching as scripture, viz.:

"Salvarsan, thou great and potent gift of the gods; thou who shinest brightest to him of dead future; thou cleanser of tainted tissue; thou saver of innocent victim of its father's forgotten lust; thou to whom arise the prayers of the multitude; thou who has led the polluted one out of the swamp of lost hope to the land of cheer, and found for him a place among men; thou who makest poison in the veins without harm; thou who makest deep sores heal, and vile scales from the body fall; thou who doest all things, and doest them well, to thee, oh Salvarsan, we make our most humble and grateful obeisance, but remember or mighty Salvarsan, remember thou well, that thou hast to make good or thou wilt be cained and sent to join the silent host of other good things that thy land hath handed us before. For verily, verily I say unto thee, forget thou not we live in Missouri, and thou has to show us."

In my correspondence with boards of health, to compile some statistics on venereal diseases, I learned from Dr. Kerr, of Texas, that there are frequent cases of gonorrhea found in colored children as young as four and five years in the South, and the April *Bulletin* of the Indiana State Board of Health reports the finding of positive gonorrhea in smears from two white girls each 8 years old and living in different parts of the State, and one living in the country. God only knows how many more cases were neither reported nor recognized, for none of us would suspect such infection at such a tender age.

We wonder how these children could become infected, and I will answer with one whack at the demon; it is because we are allowing venereal poison to get too strong a hold upon this country.

Very many young children have a crude idea of sex, an idea far more complete than is suspected, and at the same time filled with absurd notions, and there are far more playful attempts at coition among them than is at first supposed. And there are many women who seduce lads of tender age, like that street fair woman that was here last spring, of 30 years, who had persuaded a boy of 14 years old from a neighboring town. Some wish to avoid the danger of impregnation, some from strange sexual perversion, and of this class we find many of those known as clandestine prostitutes, women of seeming respectability, who are chaste as ice to the home folks, but who consort with the drummer and other transient strangers.

These women pass infection down to the lad, who in turn contaminates the little girls,

I am giving you these combinations as one of the probable manners of contagion, and there are many other ways it can be done, for I do not believe that in the main, that genital gonorrhea are contracted only by sexual congress, while syphilis can be contracted in many other ways. Rural routes, the telephone and the automobile are rapidly increasing the danger of venereal infection to our rural towns and to the country, so that to-day there are to be dangers in our rural communities. Infected women not even suspecting their condition, spread the poison without restraint.

However, the cities are the dreaded hot-beds for these diseases. In 1901 the physicians of New York reported their cases of the two venereal diseases, and while under such a system of reports many would escape notice, there were reported a total of more than 800,000 cases. Think of this. That means that one person in every five of that population suffered from this infection. Besides, those others who were not noted, may amount to a like number.

When we know that 80 per cent of the women who are sent to the operating table for the rapidly increasing pelvic surgery, are so sent as the result of innocent contamination, and that too, without their being enlightened as to the cause of their suffering.

When we pause to consider the countless multitudes who suffer in silence and in ignorance of the cause, it seems that the doctors of this country should educate the people, so they may be awakened from this state of lethargy which, like a vampire, is sapping the vitality of the nation.

There is an old book that tells of those who "Strain at a gnat and swallow a camel," and that is exactly what we are doing when we report the trivial contagious maladies, and then sit still and suffer the arch enemy to creep his sly trail without warning, and through a false idea of ethics, hide his tracks, to the best of our ability.

We notice that some of our states pass laws that require applicants to secure a health certificate before a marriage license can be issued, that he is free from venereal disease. That is a good law as far as it goes, but we all know that any good fellow has a doctor friend that will doubtless issue this certificate without ever making a thorough examination.

While this is a good law as far as it goes, but should not the man who is ill with the venereal diseases be quarantined till he is well, and then it will be far more safe for all concerned.

The Rittenhouse tables show that death from obscure forms of heart, brain and kidney affections has increased 131 per cent.

since 1880, and the same results were shown by the Yale Hospital investigations, and that these conditions are mainly gonorrheas of long standing.

What Germany has done for smallpox, what our Government has done for yellow fever in Cuba and Panama, can be done with this worse scourge of the human family by quarantining as we have done with smallpox. All that is required is that we shall cease the false "damning prudery" that acts like a silly ostrich, which hides her head in the sand and thinks herself safe because she cannot see her enemies.

Suppose we had waited to educate the people before we passed laws for the quarantine of smallpox and yellow fever. It would have been several centuries before we would ever have suppressed these diseases. So it is with venereal diseases, we can't afford to wait to educate the people, for they do not understand the danger, the risks they encounter each year, and the disease will keep spreading faster, as time passes swiftly by, from one generation to another. We who are in position to know what the country needs, should have such laws passed to protect the people and give them the best protection for their health and comfort that medical men can advise.

It is a sad mistake to think that only certain people that are in the low walks of life have gonorrhea, for nine men out of every ten have it, or have had it, or will have it, and physicians desire as much as possible to treat the best people. They do not care to be called the 'Clap Doctor.' It does not have as high ring as most doctors like. It is hard to cure, and our patients will not stay with us till they are well cured, and they will go off to some quack or druggist where they can get it cured (?) cheaper.

Eighty per cent. of the married men in New York, are said to infect their wives with gonorrhea at some time, and women, married or single, put off going to the doctor with this disease for various reasons, and they go along treating themselves till the disease passes into the cervix, and female organs, and then land on the operating table for the last resort for health.

Venereal diseases are responsible for more invalid women than any other one disease. It is causing more childless women, and more suffering than any other one disease. When I think of the innocent wives who are made invalids, and the innocent and helpless children made blind, by these terrible diseases, it makes me shudder, and cry, "My God! my God! why hast thou forsaken us."

If people knew about these things they would avoid them more, for no remedy is as good as prevention; but as long as people

whisper around that gonorrhea is no more than a bad cold, it will help to lend a helping hand to spread all forms of venereal disease.

Why will the public be so concerned about smallpox and yellow fever, and look with so little consideration upon venereal diseases?

Such conditions in live stock would not be tolerated by any self-respecting farmer of Kentucky. A striking corroboration of this fact is found in a recent number of the Louisville Times. Ten head of beef cattle shipped from Owensboro, Ky., to Buffalo, N. Y., were found by the government inspectors to be infected with itch. The Government's inspectors did not wait to examine the Federal Constitution, they did not consider that the personal liberties of the cattle or the citizens of Daviess county were being infringed upon; they did not stop to quibble about state rights. They asked at once, what steps Kentucky would take to stamp out the disease. The right of the Federal Government to protect the live stock of the country against infection is conceded by all.

Yet in one city last year 400 school children were found suffering from lice, and not one statutory law could be found to prevent the condition. The only thing that could be done, was an organized attack as an unwarranted invasion of personal liberty, to have the school inspected.

What is the stage of civilization in a nation which uses the whole force of governmental authority to prevent itch in cattle, but which hesitates to protect its school children lest it be said that individual liberty is thereby trampled on. We can only exclaim, "Oh, liberty, how many crimes are committed in thy name."

Seriously, is it not time we ask ourselves, as citizens, how many of our school children does it take to be worth one cow from Daviess county?

And again, how much more are the cows of our country worth than our children, or our neighbor's children?

We protect our country from smallpox, scarlet fever, diphtheria, and yellow fever, by the laws of our government, but not one law has ever yet been passed to protect us from the venereal poisons which are far more dangerous than any of these other diseases.

We have another step farther on, preventable blindness, in an issue of the Monograph Series of the American Association for the Conservation of Vision. The chief article in this issue is a study by the Research Department of the Boston School for Society Workers on Ophthalmia Neonatorum. The enlightenment of the profession and of the public on this important question is a work to receive the aid of all, and we are glad to see this much of a step taken, but to my mind, it does

not strike at the root of prophylaxis, like quarantining the first of the infection.

In the past, individual physicians and local medical associations have brought a scattering fire on the inactivity and ignorance of the general public in matters which pertain to public health, but at present the public seems to prefer to jeopardize its most valuable asset, by not having laws passed to protect them from the worst infectious diseases we have to combat in this country. Communities are willing to pay the cost of epidemics, and will even pay for engineering services toward public utilities, such as water supply and sewerage disposal, but when it comes to passing laws to protect them from venereal poison, then we are up against a proposition.

Why is it then we can not get representatives to take up the "poor man's burden?" The whole nation is waiting to see what action our representatives will take to protect our most precious assets, "our future generation of children."

The Committee of One Hundred of the American Association for the Advancement of Science, has given sixteen reasons for a National Department of Health. But gentlemen, if you will notice, there is not one reason, given by that public-spirited body, to suppress the worst plague that the world has to contend with, all over this great and loved land of ours. There should be one reason why we should have the worst infectious disease of our land checked. And I think, gentlemen, that laws made to quarantine every case of gonorrhea and syphilis would be the act that our legislature could do for the prevention of the worst infectious disease we have in our land.

The public is ready to give great honor to one who has played the part of a hero in saving a life from a burning building, or a wrecked ship, and recompense is showered on him the world over, but when a doctor or a board of health acts as a hero to have laws passed to save thousands of people from the vilest poison on earth, that is carrying thousands of people to the grave each year, not one compensation is ever offered by the public, not one "amen" is said, not one "thank you" is said to those who have spent their lives in serving the public, and exposing their lives to all kinds of disease to serve the public.

People who have been sufferers of venereal diseases have always been despised, they have been neglected and hated, they have been blamed on account of their lives and health and their own conduct is said to have been the cause of their condition. But gentlemen, I know of some of our best people who have suffered from smallpox that it was not on account of their own fault, and I know in my own knowledge of some of our best peo-

ple who are sufferers from venereal disease, that are not responsible for their condition, but are afflicted on account of the sins of others, and should be protected by having laws passed to quarantine venereal diseases, to prevent them going over this country scattering their poison, and infecting innocent women and children; and innocent men too, would come in under this head or class.

Gentlemen, the infectious nature of these diseases you all know, and the contraction is easy from so many sources; such as basins, towels, tooth-brushes, kissing, and even the drinking cup, that you all understand so well. Doctors know these things and understand them, but the public mind is on stock and agriculture, and the fish, and forests, and the less infectious diseases. We have laws to abolish the public drinking cup, laws to protect live stock of our country, laws to protect fish, laws to protect game, laws to protect our forests, and laws to protect our government lands. But not one law to protect the future generations of children from the most deadly poison of diseases that the world knows anything about. Diseases that are inherited down from one generation to another.

It seems to me that our Government is interested in every public enterprise more than they are in the welfare of the health of the future children. A striking picture in the *A. M. A. Jour.*, of November 11, 1911, will explain this situation, on page 1632, and I will ask you all to turn and study it. Assuming that people will expose themselves to infection, various prophylactic measures have been used with more or less success, but we cannot have this world to run as we would like it to, and so long as there is contamination, we must meet the conditions as they are found.

Legislation, then, must be the prize, and I believe with Gladstone, that physicians will become the future rulers of nations, and that physicians are the natural attorneys of the poor, and that all social problems will have to be worked out by them. I want to get people to thinking about the specific diseases in their true light; that they are more like cancer than a bad cold and that it can be avoided and prevented, if we will take the proper prophylactic measures.

I wish to give some cases as reasons why gonorrhea and syphilis should be quarantined. These cases are here under our own observation, and each of us can ponder in our own mind the different cases we have in our individual knowledge at home and abroad.

First, a man who lives in the country, contracted gonorrhea in a neighboring town, got the infection into his eyes, while nursing his eighteen-months-old baby in his lap got the infection in the baby's eyes, the results, both

blind. Had not this man better have been quarantined the rest of his life, than to have wrecked the life of this girl baby, who is a living monument of his misconduct?

Again, a man who lives in a short distance of you all, contracted syphilis, and infected his wife, and she died leaving a family of small children, and not knowing her fate or whence it came, and now her little boys are scattered to the four winds, while the husband has been cured, and goes around and it could be well said that he murdered his wife. Would it not have been better to have quarantined him for life, or cured him?

Again, the *A. M. A. Journal*, on page 783, cites a case where a young man having a chancre on his lip, was present at a kissing party; six young ladies who were kissed by him contracted chancre, and two young men contracted chancre by kissing the young ladies that this first man had kissed. Had the original sinner been quarantined, all these cases would have been protected.

Again, a young man contracted syphilis and contaminated a young orphan girl in his town, and after her case became hopeless and on her death bed, helpless and destitute of the necessities of life, she asked him for assistance, he refused. She died a poor, innocent, helpless orphan, without the guiding hand of mother and father, the victim of a villainous brute who had infected her with the most wretched disease the world knows.

Gentlemen, I do think, if there are degrees of punishment in hell, this man will occupy one of the hottest corners of everlasting punishment.

Again, I will give you a case that will appeal to our representatives. In my first year in medical school, I met a doctor who said that he always kept a girl infected with gonorrhea to infect the representatives when the legislature met in session in his town. That he made more money while the legislature was in session than at any other time of the year. Now what do you think of a man, posing himself as a doctor, keeping infected girls to catch the men of our legislature?

Again, I will give you my last reason, as this paper is getting too long: A farmer in an adjoining county, had a fine mare that got ill and while the State Veterinary was in the county on stock service, he had him to see his fine nag. The diagnosis could not be made. So he took some of the pus from a sore on her body, and had it analyzed. The diagnosis was syphilis. On inquiry among the hands of the farm, he was informed that a negro, who was rotten with syphilis, the year before, was caught in the act of coitus with the mare, and the source of contagion was plain.

Gentlemen we should have laws passed to protect our homes, to protect our children, to

protect our neighbor's children, to protect our stock, to protect our country, to protect the future generations of children, and if I do nothing more while I live than to start people to thinking and talking, it will bring men into the fight who are more able to do more persuasive and effective work along this line of work, and laws will be passed to protect us from these dreaded diseases, and I shall not regret the time and labor I have spent in presenting this subject to you on this occasion.

PUERPERAL SEPSIS.*

By W. B. OLIPHANT, New Castle.

I assure you that it is a great pleasure for me to be with you once more as one of your members and consider it quite an honor to be called upon to write a paper so soon, when I see a majority of you follow me, yet not casting any reflections on the men who have preceded me, I see you have saved the best for the last, as I notice I am to discuss my own colleague's paper on the last day of grace. Now let's get to the subject, for to some of you it may seem a plaything, but to me it is a very important one. You may talk about your tuberculosis and your cancer, but to me the most dreaded disease, as well as the most heart-rending, is that of the mother after labor, so I have chosen for my subject Puerperal Sepsis, although, no doubt, it belongs to an older and more experienced physician than I. So, my good brothers, if I get the cart before the horse, just say what a fool he has made of himself and correct me in my humble attempts.

First let us begin with the history of this trepid disease, we are told that it dates back fifty years; but in reality it dates back about thirty years, however, only in the last few years have we been so widely informed as to its nature and causes. From its earliest beginning to the nineteenth century puerperal fever was aid to be cause by the suppression of the lochia.

In 1670 Puzos claimed that this fever was due to a metastasis of milk which flowed in the blood during pregnancy and normally attracted to the breast after delivery, but drawn to other organs or structures, especially the peritoneum with disastrous results, being proven by post-mortem examinations after childbirth.

Later on English and German observers claimed puerperal fever was caused by infection of the womb and peritoneum but could not account for it. Let me say that we owe much to Ignaz Semmelweis, who was at the time a young assistant in the maternity de-

*Read before the Henry County Medical Society.

partment of the hospital of Vienna. It was in the year 1846 that there was a great mortality in one of the wards, yet in the ward next to this one there was scarcely any, so he made an investigation and found out that in the first ward the parturient patients were attended by students who came in from post-mortem examinations with putrid products on their hands, causing this fever, while the other ward was attended by midwives, thus he saved the lives of many mothers. Twenty years later we received, with much gratitude, the work of Pasteur on bacteriology, the germ theory, and also the antiseptics to surgery by Lister, so from that day on we have become better acquainted with the etiology of sepsis, septic infection and the successful prevention and curative treatment.

ETIOLOGY.

The vagina becomes infected almost immediately after birth, yet in normal conditions it contains no pathogenic bacteria, however, streptococci, staphylococci and other pathogenic microorganisms are in the vagina before labor, if present they are diminished in virulence but under favorable conditions may grow and propagate. The vaginal canal has strong germicidal properties which serve to guard a woman against infection. They depend upon (1) cervical mucus and the bloody discharge during menstruation, (2) of the germicidal powers of the elements, (3) phagocytosis, (4) leukocytosis due to chemical action and special bacillus during and after labor.

Nature has furnished the following safeguards against infection, (1) the discharge of the liquor amnii, for what purpose? To wash the vagina out, (2) the passage of the child's body, and why? to sering the vagina after the fluid has been poured on, (3) and last, the descent of the placenta, membranes and bloody discharge.

Now let us take up the pathogenic microbes that produce local inflammation when introduced into the vagina: to make a long story short I will not introduce but one and the most important. We will call him Mr. Streptococci, which was observed in cases of puerperal infection by Mayerhofer in 1865, and cultivated from such cases by Pasteur in 1880, also Doderlin found the streptococcus pyogenes as the only infecting agent in five cases of seven puerperal infection.

How do these organisms get into the genital canal? (1) The physician, himself, when he makes a digital examination with soiled fingers, after having treated such infections as diphtheria, scarlet fever, erysipelas or suppurating wounds, he may have poison from any of them on his fingers, thereby causing sepsis to the woman.

Do not let me leave you to believe that we as physicians are entirely to blame for the infection may come from the hands of a nurse or attendant, then the hygienic surroundings may be bad, unclean instruments, the bed clothing, night dress, the mattress, vulva pad and materials used to clean the vulva, such as cotton or soft rags, the water used as a douche or that used to wash the patient.

We are also told that coitus in the last two or three weeks of pregnancy is a source of infection; leaving part of the placenta in the uterine cavity; tumors such as fibroid and dermatoid cysts and lastly the woman may have had interstitial metritis, so you see we have many ways in which sepsis can get the better of us but none we can not avoid.

We now come to the symptoms and of these we have the general and local (1) general, elevated temperature, perhaps preceded by a chill, but not necessarily; rapid pulse, physical depression, tongue coated, heavy, bad breath, intense thirst, nausea and vomiting, diarrhoea in the worst cases and a disinclination to take food.

(2) Local, foul discharge, redness of mucous membrane, ulceration and false membrane along the lower genital canal, edema of the vulva, pelvic peritonitis with an exudate. We may not have all of the symptoms in puerperal sepsis but we are sure to have some of them or, for example, we may only have the elevated temperature and the rapid pulse after labor, therefore, let us be on the lookout.

DIAGNOSIS.

It may be difficult to diagnose septic fever for some of the other of high temperature after labor, for example, malaria, yet if in doubt we may have a microscopic examination of the blood made to discover whether we have a protozoa of malarial or the leukocytosis of sepsis, with the symptoms mentioned above the diagnosis should be easy.

TREATMENT.

Whether in doubt or not, we should treat the case as if it was sepsis, evacuate the bowels so as to get rid of intestinal toxæmia and give quinine in cases of malaria, we have now treated the case not being certain of it, but not let's treat puerperal sepsis.

(1). A thorough disinfection of the genitals in this manner: sterilize your instruments thoroughly, such as tenaculum, speculum and curette, then, having done this place your patient in proper position, have her external genitals cleaned thoroughly and also clean out the vagina. You are now ready to proceed. Get hold of the anterior lip of the cervix with your tenaculum, then use a douche of sterile water, now we are ready for the curett, and use it on the uterine walls until

nothing but clean blood is brought away. If you find the wound is large and flabby so drainage is impossible, then it is best to pack the wound with sterile gauze.

GENERAL TREATMENT.

Give milk, if pulse is above 110, give digitalis, carbonate of ammonia, tr. veratrum viride, nitroglycerine, hypodermically best, and freedom from all disturbance both mental and physical and last, but not least, the very best of nursing.

Now, before closing, let me ask you older physicians to look back to the days when you first began the practice of medicine, and if you were so unfortunate as to have a case of puerperal sepsis what could have been more heart-rending than to see the young mother, with her first babe, lying and dying by degrees and you not able to save her life, but taking another feather out of your cap and being censured by those who are ignorant of the disease. It has been my misfortune to have had two of these cases and a sad misfortune it was, for in both I found out, no matter what I did, my patients died in eight days. So my friends it will be pleasing for me to know from you how to fight the battle of puerperal sepsis and with what remedies.

Before closing, let me quote from Dr. Wendell Holmes, who in 1843 laid one of the corner stones that has helped to build up our knowledge of puerperal sepsis, he says: "God forbid that any of the profession to which she trod her doubly precious life at that eventful period should hazard it negligently, unadvisedly or selfishly."

THE PUERPERAL STATE.*

By J. J. ROPMAN, Owensboro.

"The key to the management of women after labor, and to the proper understanding of many important diseases which may then occur, is to be found in a study of the phenomena following delivery, and of the changes going on in the mother's system during the puerperal period. No doubt labor is a physiological and healthy function, and during recovery from its effects disease should not occur. It must not be forgotten, however, that none of our patients are under physiologically healthy conditions. The surroundings of the lying-in woman, the effects of civilization, of errors of diet, of defective cleanliness, of exposure to contagion, and of a hundred other conditions, which it is impossible to appreciate, have most important influences on the results of childbirth. Hence it follows that labor, even under the most favorable conditions, is attended with considerable risk."

This is one of the most interesting periods of a woman's life. For six weeks a physiological process is so akin to a pathological as to require constant care and attention.

A uterus enormously enlarged and hypertrophied, must be reduced to its normal size. The vagina and vulva, flabby, rent and torn, must receive from above a foul discharge and carry it to the external world. To consider this together with the small per cent of cases of septicaemia that occur, one is forced to the conclusion that it is a physiological process and that Nature provides for all deficiencies and overdrafts.

Shortly after labor is ended a large proportion of women have a rigor, as a result of nervous shock, or as Lusk says, "it is to be accounted for by the disturbance of the equilibrium between the internal temperature and that of the external surface. It is of short duration and of no prognostic importance. Frequently the bladder is paralyzed from prolonged pressure, causing retention of urine. The bladder becomes distended and the urine dribbles away drop at a time, the viscus remaining full and causing severe after-pain. Or retention of urine may be caused by swelling of the walls of the urethra and soft parts, in which case no water escapes.

As a rule the bowels are constipated, but a certain per cent. have diarrhea, and in some cases the sphincter ani becomes paralyzed, incontinence of feces resulting.

The after-pains so much complained of by some patients are the normal contractions of the uterus to expell clots and bring about involution. They usually last from one to four days, and are in duration and intensity in increased proportion to the duration and activity of the preceding labor. On this account they are more pronounced in multipara, while they are often absent subsequent to a first delivery.

After delivery a discharge sets up from the interior of the uterus, known as the lochia and continues for about three weeks. At first it consists of blood, but after a few hours serum from the wounded parts are mixed with the blood. In four or five days it becomes of a greenish color, and emits a sickening odor, and is composed of blood cells, broken-down epithelium from the mucus membrane of the uterus and pus, and contains bacteria indicative of decomposition.

The temperature is usually elevated from 1 degree to 1 1/2 degree, and so continues for five or six days, with an intermission in the morning and an exacerbation in the afternoon. It is usually more pronounced in primipara than in multipara. Lusk attributes the elevation of temperature to the organic combustion attending the involution of the uterus, the reaction of small wounds in the course of

*Read before the Daviess County Medical Society.

the genital canal, and the disturbance attending the establishment of lactation. "A temperature of 100 1-2 degrees belongs within physiological limits."—Lusk

In contrast to the increase in temperature, the pulse often exhibits a remarkable diminution in frequency, in perfectly normal cases ranging from 60 to 70, but not infrequently dropping still lower, and may even sink to 40 beats per minute. It is usually most marked on the second or third day. It is known to be associated with diminished arterial tension, and has been attributed to a variety of causes, such as the removal of the utero-placental vessels from the circulation, entailing a less degree of labor on the heart. Repose in bed, and a disturbed action of the pneumogastric nerves.

The process of involution begins at the commencement of labor. During the rapidly following contractions of the uterus the cell elements are consumed, while at the same time the compression of the nutrient vessels cuts off fresh supplies from the oxidized protoplasm. The fatty degeneration of the muscular fibres continues after the expulsion of the ovum. Gradually the proteid substances are converted into fats, which undergo absorption. By the end of the sixth week the genital organs have returned to their normal state.

When labor is finished the woman should be allowed to rest quietly for a time, especially if she is seized with a nervous rigor, we should wait till it is over. Then the soiled clothing and bed clothing should be removed and replaced by clean. The genitals and soiled parts should be carefully washed with clean water, and dried. After all danger of hemorrhage is over, the room should be darkened and all company excluded and the patient allowed to sleep if possible. The crying of the baby, the affectionate salutations of friends, and other annoyances often become the starting points for a nervous restlessness that is difficult to overcome with the strongest soporifics. With multipara it is well to leave some anodyne to overcome the annoyance and suffering from after-pains

My instructions are for patients to get out of bed on the vessel in six or eight hours after labor is ended to try to empty the bladder. Often the bladder is partially paralyzed and there will be no inclination to urinate. To slip the bed pan under the hips may answer for emptying the bladder and may not for many women cannot pass the urine while lying supine. It will surely not allow clots and blood to pass from the vagina and uterus like the erect position will, and I think that of sufficient importance to outweigh any fancied harm that might come from being helped out of bed. If instructions as to emptying the bladder are not given it might result serious-

ly. I have called the next day and found my patient suffering greatly from after-pain and a high temperature. On inquiring found that the bladder had not been emptied in all that time. They simply had no desire to pass water and it had been neglected.

The diet should be light but nutritious. Milk, to which the nurse will perhaps seriously object, is the very best article. But if I had to sum up the whole treatment of this state in one word it would be cleanliness. Keep the woman, bed and everything around clean, no matter how often changes had to be made in order to do it. Move the bowels on the second day and use no vaginal injections.

SIMPLE REFRACTION FOR THE GENERAL PRACTITIONER.

By GAYLORD C. HALL, Louisville.

In every walk of life it seems essential that there should be certain days set apart or certain times which are properly known in the business world as taking stock.

The very universality of this custom shows its wisdom and usefulness.

Now that the legislative session has closed let us take stock regarding one of the measures which vitally concerns us as doctors and guardians of the public health. Having won the fight we should be in a very much better frame of mind to look at it from the standpoint of the philosopher, since we have the satisfaction of having been victorious at least up to the present time.

The profession owes a debt of gratitude to Dr. J. N. McCormack for his untiring activity and energy with which he pushed the fight for the public health and the profession against the united efforts of quack, charlatan, optometrists and members of the league of Medical Freedom.

At present we are concerned chiefly with the optometry bill, for we are certain that this will reappear two years from now with the same or greater vigor. It means something to the men who are after it, largely in a business way. This means money and that explains the assiduousness with which they pursue their quest.

Unless the Medical Profession of Kentucky show a corresponding interest in the matter it will of course finally go by default and the doctor will see the invasion of the field of medicine by a group of men untrained and inadequately qualified for the work, who will be placed by legislative enactment upon as high or higher plane than the doctor who is qualified.

The question thus arises, what can the med-

ical profession do in the meanwhile to render the cause of the optometrist without virtue and protect themselves from further attack?

First, what should be the attitude of the profession as a whole towards the optometrist?

It is an unfortunate fact, though nevertheless true, that at least some members of the profession demean themselves by referring to the optometrist and some have even gone so far as to openly endorse these men to the detriment of their own brethren and these endorsements have been used by the optometrists in their fight against the profession.

This occurred in our own State during the last session and was virtually the cause of the passage of the optometry bill in the State of New York.

The medical profession should be on its guard against the importunities or blandishments of these men and not be led to an endorsement of their designs, either through personal reasons or led astray by specious arguments.

In short, the members of the profession should neither refer cases to the optometrist nor assist or endorse in any way their proposed legislation.

The argument that appealed most strongly, it is said, to the members of the legislature in the recent campaign, was the point made by the optometrists that people in remote districts would not come to the city for refraction nor pay the fees of a specialist. Therefore, by refusing to pass their bill we either denied these people the help of glasses entirely or we left them a prey to the unregulated and unlicensed spectacle vendor. They did not explain why a spectacle vendor, licensed, is any more competent to administer to the eyes of patients than one who is unlicensed, yet the fact that certain people will not come to the cities nor consult a specialist regarding the eyes brings up the very pertinent question, if the average general practitioner by the expenditure of a very little time and study can not better qualify himself in every way to do simple refraction than men without any medical training.

This phase of the question has been discussed in the Section of Ophthalmology of the American Medical Association and the cause was warmly championed by the late Leartus Connor of Detroit.

A number of States have already made it obligatory for all applicants in medicine to pass an examination in refraction. This is a step in the right direction and should be extended to every State. There is no reason in the world why this branch of medical science should be delegated to non-medical men and cast off by the profession in general.

It is therefore incumbent upon the family physician to qualify himself in this respect so that he may be able to attend to that class of his patients who are beyond the jurisdiction of the specialist in eye diseases, either through diffidence, unwillingness to pay the fees of a specialist, or who live in remote districts.

It seems to the writer that it is a moral obligation of every physician to promote the interests of his clientele in every possible way. In this particular instance it seems an obligation for his own sake as well as for the good of his patients, since the traveling spectacle vendor not only knows nothing of refraction but usually is a rogue as well.

If this were the only side of the question it would appear to be enough to influence any right minded physician to interest himself in such a work. There is however a brighter side. This work is profitable. It stimulates the upbuilding of an office practice and it is work that calls for no long and arduous journeys but can be done at odd times when the physician is not otherwise occupied.

It is one of those influences for good which brings the patient under the control of the doctor to a greater degree and tends to prevent him wandering away in other side places, since if the doctor encourages his patient in consulting an unqualified person about the eyes, which is certainly a medical matter, that is but a step in the direction of self dragging with patent medicines and the dispensing with the doctor's services altogether.

It is not meant that every doctor in Kentucky should fit himself to do refraction. One man in each community, not too thickly populated, is sufficient and the doctors in that community should come to some sort of an agreement by means of which they would lend their influence towards turning the work into the proper channel instead of discommensurating any one of their number who undertook such work.

The expense of the outfit required to do simple refraction is not great. Forty-five dollars would supply any one with an acceptable outfit. If one contemplated more extensive work in that line, seventy-five dollars would be a wise expenditure. This would include a trial case with suitable frames, test cards for distance and near, a retinoscope, an ophthalmoscope, and a two-inch condensing lens. The office should admit of being darkened for doing retinoscopy and, if the physician were ambitious enough to learn it, for the use of the ophthalmoscope.

There are several methods of lighting in the absence of electricity and gas. An oil lamp with a black cover with a hole about the size of a dollar in its side would make a serviceable source of light.

In order to gain a general knowledge of the subject two books than can be recommended are, "Refraction of the Eye," by Gustavus Hartridge, and "Refraction and How To Refract," by James Thorington; both books published by P. Blakiston's Son and Company of Philadelphia.

In order to gain a practical working knowledge for the practice of retinoscopy or ophthalmoscopy there are several schematic eyes upon the market which are valuable for that purpose; one by Fisher and one by Thorington.

In order to employ the time given to the examination to the greatest advantage one should adopt a systematic method of examination. Such for instance as the direct inspection of the external eye and its appendages including the vergence of the lids, testing pupillary activity, roughly testing the degree of convergence by approaching the fingers as close as possible between the eyes before they diverge. This can be followed by the taking of the vision by test types. If vision is normal it does not exclude a refractive error. If vision is below normal it does not mean necessarily that a refractive error exists. The trouble may be due to congenital defects, defects in or behind the retina, or scars. It is therefore best to next employ oblique illumination with the fourteen diopter condensing lens making minute search over the cornea for faint macula, the result of former corneal ulcerations or injuries. These, if central, seriously impair vision.

Having determined these things we may next proceed to the examination of the refraction. If drops are employed, homatropia, two per cent., every ten minutes for an hour will generally suspend the accommodation. It may be necessary in children or in young hypermetropes to use atropin or scopolamin, the writer preferring scopolamin because it is quicker and as effective. It is employed in the strength of one-fourth of one per cent., one drop instilled and repeated in half an hour. If atropin is employed it should be in one per cent. solution three times a day for three days except in very young children when one-half per cent is sufficient.

One should consult the text books concerning the occasional systemic effect of the mydriatic and be familiar with the occurrence so that they will not be taken by surprise but can assure the patients of its harmlessness.

Following the suspension of the accommodation it is always best to employ the retinoscope and obtain the exact refraction. In all complicated cases it saves a great deal of time and gives you confidence in the results which no other method can give. Following the retinoscopic examination, examination with

the ophthalmoscope should be done. The patient is then ready for final testing at the test types.

Such detailed examination may seem unnecessarily long yet when one becomes accustomed to its employment he is surprised at the facility with which it can be accomplished and the short time it takes. It is recommended simply as a good practical work schedule.

It is not the intention of the writer nor does he wish to be construed as believing that a man doing general practice can easily qualify himself to pass judgment on grave eye conditions nor even successfully refract the more complicated cases, or rather the cases complicated with many nervous symptoms.

He does think, however, that it is within the ability of every general practitioner to know the fundamental principles of optics and the uses of lenses as well as their limitations; that they could by moderate practice and study develop into a very fair refractionist, able to undertake any simple case and better than that to understand thoroughly when they were dealing with one more complicated.

This paper is submitted to the profession of Kentucky, more particularly to the men doing practice in the rural districts and the writer asks for its earnest and careful consideration. He firmly believes he is not overstating the case and that it is highly possible that the general practitioner could so qualify himself to the lasting benefit of his community and himself; from the standpoint of health as well as in a material way.

The taking up of such work by the requisite number of general practitioners in the State would be the practical solution of the optometry problem and would put the profession upon a higher scale.

PROPRIETARIES VS. OFFICIAL DRUGS OR, U. S. P. & N. F. PREPARATIONS VS. NOSTRUMS AND PROPRIETARIES.*

By S. H. WINSTEAD, Druggist, Paducah.

Being truly in accord with my profession; pharmacy, and in sympathy with your profession, I assure you that it was with rare pride that I accepted the command of your Honorable Secretary, Dr. H. G. Reynolds, to read a paper before you upon this occasion. But when the subject of "Proprietaries vs. Official Drugs" was allotted me, I was literally swamped, because of the enormity of this most important subject, for it has so many avenues of approach that I hardly know

*Read before the Southwestern Kentucky Medical Association, May 22, at Paducah.

where to begin. However, I beg your indulgence for a short while this morning, during which I will attempt, in my feeble way, to present to you a few of the important phases which have impressed my mind.

If any two professions on earth should work in unison, they are the doctors and druggists. I'm sure that we are all of one mind on the question of harmonious activity between the pharmacist and the physician. To labor harmoniously means greater achievement for both professions and the more we strive to perfect that relation of harmony and united endeavor, the greater will be our success. We are working for one common good; our ultimate goal always has been and always will be, the alleviation and cure of diseases of our fellow man, and the tie that should bind us in this glorious work, can be made no stronger than through the means of the U. S. P. & N. F. propaganda, for gentlemen, the day of worthless and useless nostrums and proprietaries is nearing its end. They have been weighed in the balance and found wanting. Therefore, let me urge that we turn our attention to the sunrise of to-morrow, when we can hope for far better things, both in medicine as well as in pharmacy.

You doubtless are well aware that there is much self-medication practiced among the laity to-day and I am frank to say that the doctors and druggists are both to share, and share alike, in this lamentable condition of affairs. To further neglect remedial measures would serve to retard greatly much that we would build up, therefore, it behooves both professions to take stock, as it were, see where-in we are deficient, then make an honest and determined effort to right the wrong, for we owe it to ourselves and to our patients.

Just for example: a physician writes a prescription for a bottle of some proprietary remedy, with usual directions. It is a short name. The patient remembers it, since in this day, a great percentage of the laity are proud to familiarize themselves with the terms applied to diseases and medicines. The patient chucks the prescription into the discard and sallies forth to the druggist, asks for a bottle of the proprietary and then takes it according to the directions. It is only natural to assume that that patient, especially the discerning one, will eventually tell his friends and neighbors of his experience and recommend the purchase of a bottle of the same medicine, explaining that Doctor So and So prescribed it for such and such a malady, and before you know it doctor, you have inaugurated the sale of what was once a proprietary, and finding yourself responsible for the general sale of a regular patent medicine, when, if you had written an ethical prescription, it would have been filled and taken, and thereaf-

ter regarded by the patient with the respect that is its due. An extreme case was related to me by a responsible person who once saw a prescription for tinct. nux vomica, 2 drams: Pinkham's vegetable compound, 8 ounces: with directions 2 teaspoonsful 3 times a day. Now in what light do you suppose the druggist regarded the physician responsible for such a prescription, and worse still, what regard could the discerning patient have for the doctor? Such a practice is deplorable. If it were possible for you doctors to spend a while in the prescription department of the drug stores of to-day, you would soon become disgusted at the vast amount of prescriptions for patent medicines, but I am glad to say that conditions are rapidly improving, and let's hope that some day, all prescriptions will be of the U. S. P. & N. F. composition. I could stand here for hours and name hundreds of patent medicines which have been introduced to the public as proprietaries owing to the indiscretions of the doctors. Such a practice gives some druggists enough leeway to recommend these remedies to his customers, but this is a very poor excuse and should not be tolerated.

A casual study of the U. S. P. & N. F. would soon convince you that they contain formulas for preparations which must be made of a uniform strength from tested drugs of known medical value, for these formulas are written by the Pharmacopoeial Committee and the National Formulary Committee, and over 60 per cent. of these committees is composed of practicing physicians, the other 40 per cent. of druggists of national reputation. The committees, after careful and honest work, have endeavored to give to the physician, preparations which will be worthy of his consideration, and which can be compounded correctly by any intelligent druggist. While along this line, let me add that the cost of your patient's prescriptions would be decreased not less than 33 1-3 per cent. for, gentlemen, the proprietary fellow is not in the business for glory. It is the almighty dollar he is after, and he always taxes us to the limit for his goods, thereby imposing upon the patient, a cost nearly double the price he would pay, if these prescriptions were of the U. S. P. & N. F. variety.

There is no wonder that the unthinking doctor rates the druggist as a merchant of the average in intellect, when your medical colleges give their students lectures in pharmacy for only eight weeks, two lessons each week, and after giving them these sixteen lectures, they dismiss the subject, saying that that is all there is to pharmacy. There is no finality in pharmacy, but no wonder, with this feeble information, the young doctor launches his career in practice with such a

menger knowledge as to pharmaceutical preparations. I say that it is no wonder that he falls victim to the designing proprietary manufacturer.

The National Association of Retail Druggists are doing a great good among the doctors at regular intervals. The official preparations are those the formulas of which are given in the U. S. P. and the N. F. the standard of the United States in the way of books of reference. If you will stop to think, you will realize their importance, for these formulas are the finished product of the minds of the foremost authorities in the world. They have been endorsed by the Revision Committee, about 60 per cent. of which are physicians, as I stated before.

Allow me to recite to you ten cardinal strong points of these official preparations, as formulated by a prominent Chicago druggist:

1. They are created primarily for therapeutic value and not for profit.
2. They are not exorbitant in price.
3. They are of certain and reliable compositions, the formulas being given in every detail, even to the method of manufacture.
4. Being standard, their compositions definitely known, they cannot be altered to suit the manufacturers whim or pocket book, the manufacturer not controlling them.
5. Knowing the exact ingredients, the physician does not prescribe contraindicated drugs.
6. Not being accompanied by circulars and not having short names, they are not easily read and remembered, and therefore do not lead to self-medication.
7. They are not advertised to the public, over the physician's head.
8. Knowing their exact compositions, the physician avoids incompatibilities both physical and chemical, also the prescribing of two or more preparations containing the same active ingredients, thereby avoiding dangerous mixtures.
9. The formula being open, the physician knows what he is prescribing and therefore, knows what therapeutic results to expect.
10. They can be prepared by all capable pharmacists.

Now as to proprietaries. You are never furnished with a complete formula. If you were, there is no moral or legal assurance that this formula is always adhered to. It is subject to change without notice. There is no standard set down by authorities. You think you get results, but to save you, you cannot tell what produces them. Gentlemen, you cannot administer intelligently to your patients when you resort to treatment with patent proprietary medicines. I thank you for your attention and I really long for the day to

come when such ideal conditions as both professions could picture, can be realized.

Now in conclusion, I want to say in the beautiful language of my friend H. C. Shuptrine of Georgia, and his words will bear repetition many times over, that

"None appreciate more your hard and thankless work, your anxiety, than do we druggists. We realize your hardships as well as your comforts; your sorrows as well as your joys; your hours of rewarded ambition and your hours of hopeless despair. We realize that in your disposition, you must be as flexible as a silken cord, as irresistible as a cube of tempered steel, yet as tender and subtle as a flower that in its perfume gives to the morning air its first breath of spring. To the mother, father and child, your presence is as a shrine, for in you is placed all their earthly faith. When you raise to health or lean over the death-bed of a dying babe, you sound those tender chords of motherhood, the resonance of which is heard back in even sweeter cadences, the music of the 'Far-Beyond.'"

Gentlemen, I thank you.

DIET.*

By C. H. Tonn, Owensboro.

In preparing this paper on "Diet," I have not been unmindful of the advice given by a distinguished medical writer: "have something to say, say it, and stop."

It is a remarkable fact, that the bedside practitioners of to-day, still follow in the footsteps of their predecessors, in the concentration of their minds upon the treatment of disease by drugs, almost exclusively, with little or no thought of the diet, when in fact diet is often as important, or more so, than drugs in the treatment of disease, especially fevers.

It has been truly said that the principles of nutrition are better known than the way to apply them. Our use of foods has been much less accurate than our use of drugs, and dietary mistakes have been common, through ignorance of food values, or difficulty in estimating them.

In fevers and other conditions where a liquid diet is largely used, a knowledge of food value is very important, for there is great difference in the food value of different liquids.

In making a comparative table of estimates, and in using the term "calories," I wish to consider this term as units, or molecules of heat. First, one glass of unskimmed milk equals 160 calories; 2nd, one glass three-fourths unskimmed milk and one-fourth cream equals 240 calories; 3rd, an egg-nogg,

*Read before the Daviess County Medical Society.

composed of one glass of unskimmed milk, one egg, and two teaspoonfuls of sugar equals approximately 300 calories; 4th, a plate of cream soup equals 160 calories.

We will consider the food value of those liquids so commonly used by physicians, especially in fevers: 1. A glass of skimmed milk or buttermilk equals 80 calories. 2. An equal amount of gruel equals 75 calories. 3. A glass of albumin water (white of one egg) equals 20 calories. 4. A cup of beef tea or clear soup equals 5 to 20 calories.

Let us take a 150 pound patient in bed, who needs approximately 1800 calories a day, and who receives ten feedings of a glass (8 ounces) of liquids a day. Some combinations of liquids, allowing for agreeable variety, will abundantly nourish him, while other combinations mean partial starvation. 1. Two glasses each of unskimmed milk 320 calories, gruel 150 calories, thickened soup 320 calories, egg-nogg 600 calories, milk and cream mixture 480 calories, total 1870 calories.

Such a liquid diet in fevers, will materially retain the weight and strength of the patient, but unfortunately to-day, physicians are apprehensive, less their patients receive too much liquid food value, and so we submit the table generally used by most physicians, especially in typhoid fever: 1. Two glasses each of unskimmed milk equals 320 calories, buttermilk equals 160 calories, gruel equals 150 calories, albumin water equals 40 calories, and beef tea or clear soup equals 20 calories, making a total of 690 calories, being one-third of the quantity of liquid food value needed to support the patient, and when such diet is given to fever patients or invalids, the loss of weight is attributed to "wasting disease."

I hope you will pardon me for being personal, when I assert that every physician in this audience can recall instances, in their practice, wherein they relied, exclusively, upon skimmed milk, buttermilk, gruel, albumin, water, beef tea or clear soup, a diet containing less than one-third of liquid food value sufficient to sustain their patients, and at the time little did they imagine that, with the use of such diet, they were simply hastening the departure of their patient "over the river."

I am frank to confess that I can recall many, many, many dozens of similar instances in my own practice.

It has been creditably shown how it is possible, to give typhoid fever patients 1000 to 5000 calories a day, on a diet of milk, cream, ice cream, sugar and eggs, without disturbing digestion, and to carry them through their fevers, with little loss of weight.

Some years ago a case of typhoid fever was reported by a member of the Owensboro Medical Society, which was freely discussed

by all the members present. The patient was a man sixty years old, in the seventh week, temperature below normal, rapid, weak pulse, 30 to 40 stools every twenty-four hours, greatly emaciated, abdomen retracted, resembling an old-fashioned buck-eye bread-tray, and patient forced to lie on his back, as turning on either side produced extreme pain in the abdomen and more frequent stools; condition extremely grave, all else having failed to check the bowels, was given 1-4 grain of morphia and 1-150 grain of atropia, hypodermically, every 3 or 4 hours; patient cyanotic. The diet was skimmed milk, buttermilk, gruel, albumin water, beef tea or clear soup and stimulants.

The following treatment was advised and accepted by the attending physician: Stop all slops and hypodermics, and in lieu was given breakfast middling, corn cakes, ice cream, coffee and stimulants, and twenty dops of landanum in one tablespoon of starch water, gently injected into the rectum every three or four hours, using a two ounce piston syringe to relieve the tenesmus; foot of bed raised 8 or 10 inches; a woman's flannel skirt, folded into a pad 6 or 8 inches thick, and forcibly retained over the abdomen by a wide bandage.

The attending physician reported that during the first twenty-four hours there were only three or four stools, and the patient could rest comfortably on either side, and was soon convalescent.

This was a case of relapsing typhoid fever, so called, but in reality a fever of inanition, which was due to the want of sufficient nourishing liquid food to support the patient, from the inception of the fever.

It has been my experience that typhoid fever, continuing after twenty-five or thirty days, becomes, not a relapsing fever, but a fever of inanition, and for some years I have given freely of nourishing liquid food in order to prevent this fever of inanition, thereby preventing the great loss of weight and nerve exhaustion.

Instances of the fever of inanition from thirst are almost daily recorded—shipwrecks and entombed coal miners—the temperature rising after the first day, and at the end of the third and fourth day the man often becomes a raving maniac with a temperature of 104 to 106 degrees Fahrenheit, the fever of inanition due to the want of water.

As late as fifteen years ago, the abdominal surgeon, after a laparotomy, deprived his patient of water for three days, and the first complaint of the patient was intense thirst, due often to the loss of blood, or shock, and especially by the action of the anesthetic on the air passages, causing dryness and burning of the throat. The suffering of many of

these patients was terrible, and being deprived of water produced a fever of inanition, which often was construed as surgical fever.

Fecal impaction due to neurosis of the intestines, a condition often the bane of the abdominal surgeon, is promptly and successfully relieved by the free ingestion of coarse solid food, boiled cabbage and fat middling, jowls and greens, corn bread, etc.

The fever that occurs, whether a high or low temperature, is a fever of inanition.

The only drug required in these cases is the syrup of the hypophosphate of lime and soda, to replace the basic salts, as the patient's system is below par.

This paper will not admit of my considering the diet of diabetes, in which the ingestion of foods, containing carbohydrates, must be used sparingly, nor the diet of nephritis, in which the ingestion of foods containing proteids must be used in moderation.

BIOLOGICAL THERAPEUTICS IN PYORRHEA ALVEOLARIS.—AUTOGEN-IC METHOD.*

By J. H. Wood, D. D. S., Lexington.

The subject upon which we are about to touch is one that has always been in the past looked upon as a ghost in the list of diseases that come under the observation of the dental profession.

Many, probably all of us have attempted to discover its mysterious origin or to determine its diathesis. In this many of us may think we have been successful, and have at once had dreams of the time when our reputation as "the dentist" who can cure pyorrhea alveolaris has become so great that we can begin to specialize in this work and save not only the teeth, but in so doing protect the health of all who come to us before it is too late.

As a rule, however, we awaken from our dreams before they become nightmares because some other investigator comes along with a theory widely different from our's and shows us that we are wrong, or because we find that the case we thought we had cured of pyorrhea was not pyorrhea at all, but something that would have gotten along all right anyhow if the proper prophylactic measures had been taken, and our treatment left off entirely.

Every time we cleanse a filthy set of teeth and find a little pus at the margin of the gums we are too prone to decide at once that we have found a true case of pyorrhea. This frequently is the condition found, but it is frequently not the condition that we are led to believe that it is. These cases of mistaken diagnosis are the ones that tend us to believe

that we have found a sure case for this wide spread and unconquered disease, when in reality a little clear water combined with a good brush and a vigorous brush massage twice or three times a day would probably bring about better results than our medical treatment.

At present the medical profession is very enthusiastic about bacterial vaccine treatment for the cure of all localized infections of a low grade, such as ordinary skin eruptions, boils, ulcers, acne, gonorrhea and such. This enthusiasm seems very justifiable according to the results obtained. Old infections that have baffled all previous treatments applied have yielded very readily to the action of the bacterine solutions. If these infections yield to the bacterine treatment, there is no legitimate reason that pyorrhea alveolaris should not be a typical infection in which this treatment is indicated.

Biological investigation has shown beyond a doubt that this is a bacterial disease and judging from the fact that the pus is always discharged round the gingivae, even when the pockets are deep seated instead of boring through the alveolus and gum as in the case of dental abscess, leads us to infer that the bacterin are of the pus-forming variety known as the staphylococci, and it is the general idea where investigation along this line has been made that this disease germ is either the staphylococcus albus, aureus or citreus, or at times a mixed infection containing any two, or probably three of these.

After having made a very careful study of this disease in a bacteriological laboratory equipped for the purpose, and with the use of the laboratories of the State Universities offered to me to use at any time, I have come to the conclusion that the pus from the pockets around the teeth affected with pyorrhea alveolaris may contain not only one or all three of the staphylococcus albus, aureus and citreus, but contains practically at all times the streptococcus pyogenes, this latter being the bacterium of dental abscess.

Pyorrhea never forms a fistulous opening on the gum for the reason that the deep pus pockets are formed after the ravages of the disease have already made an opening from the gingival border to the seat of the deep pockets, allowing the pockets to drain through that channel thus averting the boring action of the streptococci.

The bacteria mentioned attack the alveolar periosteum, after the destruction of which the alveolar process is left in such a condition that it remains a constant source of irritation to the surrounding tissues until it is absorbed or removed mechanically.

A sharp edge or point of one can frequently be felt with the probe as we are exploring

*Read before the Kentucky Dental Association.

the deep pockets of a badly affected alveolus. Such points cause the soft tissues circumjacent to become congested and sore. The gums bleed easily and the patient thinks that it is the wrong thing to brush them when brushing makes them bleed, hence we find in most cases that have reached this stage a filthy condition to make matters worse.

Frequently other bacteria are found besides the ones mentioned, in a culture from a pyorrhea infection, but are generally recognized as some germ, or the same ones occur so seldom as to preclude the possibility of its having anything to do with the infection.

Thus far we have touched only upon the disease and its conditions as we find them after the infection has become well developed. The treatment usually relied upon in the past has been practically uncertain, or we might say practically certain not to cure pyorrhea. There is no doubt that the ravages of the disease have frequently been checked, usually for a short time, then we see the same old trouble only just a little bit worse than it was before. The reason is simple. The system is not fighting the disease and we have only been making the vigorous little bacteria sick with our treatment instead of destroying them.

The white blood corpuscles or phagocytes are the soldiers that guard the body against infection, and whenever any infection becomes malignant it is because the phagocytes for some reason are not doing their duty, or have by some means become overpowered.

If we now examine the white blood corpuscles under a powerful microscope, we will find them to be inert as far as the bacteria in question are concerned. You will not find them laden with the germs they should be fighting to destroy.

Science has determined that the power of the phagocytes is due to the presence of opsonins in the blood. The duty of opsonins seems to be to capture and deliver to the phagocytes for destruction the invading bacteria before they have a chance to cause infection, and by this means prevent them from causing any local or systemic trouble. If we have a patient with pyorrhea alveolaris and examine the phagocytes under the microscope, we will find none of the bacteria causing the infection engulfed therein, showing that something is lacking to cause the guardians to do their duty.

It has been found that the introduction into the system of bacterial vaccine favors phagocytosis by increasing the opsonins in the blood, thereby raising the opsonic index, thus increasing or raising the low resistance of the system to that particular germ, to a high resistance. This will be shown to be the case if you will after introducing the vaccine and waiting a sufficient length of time, again ex-

amine the phagocytes under the microscope. You will now find them laden with the very germs that you want then to destroy, which shows that the system is beginning to rid itself of the bacteria that are causing the infection that we have under consideration.

In the treatment of pyorrhea alveolaris by the vaccine method I believe it to be imperative to use the autogenous bacterine, as the infections are so mixed as a usual thing, and there are so many strains of the staphylococcus and the streptococcus, that the use of the stock vaccines would seem to indicate failure. We must bear in mind that germ life is something that is greatly influenced by environment, and a bacterine made from the infection to be treated will be more likely to be able to combat the individual characteristics of the germs which cause that infection.

Unless prepared to make autogenous bacterine ourselves, it is strongly advisable for us to get some competent bacteriologist to make it for us. It is work that entails great care and a thorough knowledge of the technique, for there are quite a number of side issues besides the simple incubation and emulsification that demand our most careful attention. If we are considering the staphylococcus, as we surely must in the case of pyorrhea, we must not forget the discovery of Van der Veldt, who found that staphylotoxins cause hemolysis. Nearly all of the pathogenic species of staphylococci yield these toxins. It is not formed by the non-pathogenic species. These toxins are destroyed by exposure to a temperature of fifty-six degrees centigrade for twenty minutes. The hemolytic toxins formed by certain streptococci have been known to take a temperature of seventy degrees centigrade, continued for two hours. Hence we see that while extreme care is necessary, we can by careful technique eliminate all danger.

The technique of administration is very simple. Every aseptic precaution must be observed of course. To cleanse and sterilize the syringe is the first step. I use an all glass or all metal syringe that has no soft packing of any sort. These may be boiled without any danger of injury to them whatever. The skin at the point of injection should be cleansed with some antiseptic solution immediately before injection, and immediately afterward. Alcohol is very good, or the place may be painted lightly with iodine. Always choose some place for the injection as far as possible from any glandular locality. I inject between the shoulder blades, first on one side, and at the next operation on the other side.

The standardized solution contains about 500,000,000 bacteria to the cubic centimeter. The initial dose should not exceed 100,000,000 bacteria, or one-fifth of a cubic centimeter of

standard solution, in a normal saline solution sufficient to make one cubic centimeter. I have found the normal salt to act as well in every way as the physiological solution, and it is certainly much easier to make.

The local and physiological reaction of the patient should be closely observed, especially after the initial dose, and the temperature and other manifestations indicating a negative phase should be carefully noted and used as an index for the size of the next dose.

After the initial injection the temperature generally increases slightly, followed by a slight headache and backache some time during the first twelve hours after the administration. This is usually followed by a feeling of buoyancy. The local reaction manifests itself by an indurated area about the size of a dollar or smaller, according to the size of the dose administered.

Never increase the dose as long as any reaction occurs. Rather decrease it and then gradually increase as the patient can stand it without showing any reaction at all. We should never be in a hurry. The best results are obtained by taking all the time needed and very gradually increasing the dose until no reaction can be obtained no matter what amount of bacterine we inject. The pus will disappear and unless the bony support of the teeth affected has been entirely destroyed, we will be rewarded by seeing them gradually tighten nicely, and resume their normal functions. Any tooth that may be loose on account of lack of alveolar attachment should be splinted and given a chance in that way. One-third of the alveolar attachment left in good condition is very frequently sufficient to hold the tooth firmly enough for it to perform its normal functions.

Of course the teeth must be thoroughly sealed at the beginning of the treatment, and every particle of calculus must be removed, no matter how far up on the root it may extend. The use of ammonium bithioidate or aromatic spirits of sulphuric acid, properly applied, is recommended to sterilize the pus pockets and to remove any small scales that may have been missed by the sealing instruments. All sharp points of unabsorbed process must be removed or smoothed so as to be non-irritating. Bacterial vaccine will bring about the destruction of the bacteria involved, but as long as a constant source of irritation remains present, the teeth will never tighten, and the gums will remain soft, congested and spongy.

Local treatment and prophylaxis are necessary if we expect to obtain the desired results from biological therapeutics.

As pyorrhea usually accompanies arthritis, or other diseases having a gouty diathesis, it would seem to indicate that the patient should be put on a non-nitrogenous diet.

My clinical experience with this method of treatment has been limited, but with the cases that have presented and have been finished, the results have been most satisfactory, both to the patient and myself, and it is only reasonable to believe that the opsonic index once raised, and the phagocytes stirred to action, that they will keep up the work of systemic sterilization in regard to the infection that we have been treating, until the last bacterium has been disposed of. That this treatment will render the patient immune to future infection, I firmly believe, and can refer to such authority as Dr. Ehrlich.

The repeated injection of bacterial vaccine into the system will produce a blood serum containing immune substance called bacteriolysin, produced by the endo-toxins carried by the bacterine, which is specific in the destruction of bacteria of the same species.

INFANTILE DIARRHEA.*

By R. N. FILATREAN, Knottsville.

Diarrhea is frequent during the whole period of infancy up to the third year of life.

Many writers describe many varieties according to variations in symptoms. I think the whole thing may be classified under three heads so as to embrace practically the whole string of symptoms. Letting all those finer distinctions of the ultra scientific be embraced under the head of

1st, Simple Diarrhea—Intestinal catarrh or entero colitis and cholera infantum.

Simple diarrhea often comes on suddenly, but sometimes is preceded for a day or two by restlessness, disturbed sleep, nausea and vomiting. Causes are various. Conditions or agencies which have no appreciable effect in the adult often increase the number of evacuations in the infant.

Food which imperfectly digests, some of which ferments, stimulates the intestinal follicles to excessive secretion and increases the peristaltic movements by its irritating action, thus causing diarrhea.

Too frequent and abundant feeding is another cause, especially in young infants; some of whom may vomit the surplus food and remain well, but others do not. Food which cannot be assimilated, becomes an irritant in consequence of fermentation or by its mere presence there in the intestinal canal a foreign unassimilated body, becomes an irritant and sets up diarrhoea. The mother's milk may disagree either from some temporary derangement of her system or continual ill health. Diarrhea in the nursing infant is the result.

Fright or strong mental impressions will

*Read before the Davless County Medical Society.

also in some children increase the number of evacuations. Exposure to cold may also be a cause, children who are insufficiently clothed in the winter season or who are taken from a warm room into a cool one without sufficient protection; or who lie uncovered at night, are subject to diarrheal attacks from the impression of cold on the system. The cause of the diarrhea may exist in the child itself. In some children the evolution of the teeth is attended by a relaxed condition of the bowels, which ceases when the gum is pierced; whether it is the cause of the diarrhea or not.

Intestinal worms also may operate as a cause. Diarrhea is occasionally salutary within certain limits, especially if occurring from the presence of excessive or irritating food it is obviously conservative.

The stools in simple diarrhea differ much in color and consistency in different cases and perhaps at different times in the same case. They contain particles of casein or any other residue of undigested food.

Stools are usually passed easily but if they be acid or in any way irritating there will be more or less tenesmus, especially in young infants.

During the quiet hours of sleep, when no food or drinks are taken the diarrhea diminishes. There is much or little thirst in accordance with the severity of the attack, if the actions are frequent, thin and watery and rather long continued, then thirst is greater.

The features in this disease are pallid. In a few days, if the evacuations continue, there is evident loss of flesh and weight, the tissues become soft and flabby, and the roundness of limbs is gradually lost; but in most cases when the malady has reached this stage its original character is lost and it has become inflammatory. Certain symptoms may occur here as well as in the inflammatory stage such as sympathetic cough, or what is more serious, cerebral complications, convulsions or stupor indicating the supervention of spurious hydrocephalus and this may occur in either form of diarrhea.

In a large proportion of cases simple diarrhea, when properly treated, is not dangerous; and just at this point I deem it appropriate to digress just a little from the beaten path to assert that though the handling of these simple cases seems so rudimentary, as scarcely to warrant space in a paper or time in discussion, so simple that the laity seems to feel able to cope with this trouble without the cooperation of the physician; and yet in my opinion the most of the serious bowel troubles and complications, especially as we see them occurring in the country, take their rise from poorly managed and improperly treated simple forms of diarrhea.

Realizing that often, despite appropriate

treatment, and our best directed efforts some of these simple cases go on into the more serious forms and from that on into a long, tiresome, wasting illness and dangerous in the extreme because so many of them, even after the most anxious and arduous attention and unswerving devotion of attendants, the little ones are torn at last from the loving embrace of devoted parenthood and by the grim angel consigned to a celestial home.

Then I doubt if simple diarrhea is so simple after all; I doubt the appropriateness of encouragement of the laity to continue trying to handle these cases. I hope the days of the old woman's black oak bark ooze or black berry bush root juice, or the landanna route, or the various patent and proprietary nostrums foisted on an unsuspecting and ignorant public by the mercenary quacks, too numerous in the land, who proclaim their remedies the great infallible cure-alls. I hope these days will soon come to an end. For when these simple cases have been ignorantly tampered with, and the simple condition has thus been allowed to go on and assume more serious forms, then indeed have the parents, the physicians, and all concerned, something to contend with.

Too often does the physician carry the blame in the minds and mouths of the parents and friends, because of the untimely shuffling off of one of the innocents. At the same time this sad event is directly due, too often, to faults of omission and of commission of the very same parents who blame the doctor. And how is this? Why a simple diarrhea is at the suggestion of some kind-hearted old grandmother, or ignorant, but wise and kind-hearted acquaintance, shut down by one or the other of a thousand home-made or ready-made concoctions; the irritative material or whatever is causing the diarrhea, is locked in the intestines, further putrefactive and fermentative process take place, a fresh diarrhea takes place, nature is fighting the disease and trying to annul the wrong treatment; but the diligent friends and anxious mother get busy again with the same old plan or else try another which has a similar action only to shut up nature's safety valves, and lock in again the various poisons and irritants, directly after two or three or four of these attempts a real infection occurs; inflammatory processes have started up, there is fever, vomiting, great exhaustion on the part of the child; great anxiety on the part of the family and friends; a physician is called in, most likely in the night, and if he fails to get the damage already done, repaired in a very short time he is either discarded as no good, or else his instructions are but poorly and half-heartedly carried out; his directions as to diet are most woefully disregarded, the treatment he rec-

commendations may be given, and it is highly probable that even while employing the doctor they are at the same time surreptitiously giving something of their own, or their friends' concoction.

In such cases it is not difficult to guess at the result. The physician has lost out, the parents are bereaved and the baby has gone to join the angels.

Now do not understand me as meaning to imply that this practice of disregard to diet orders and extra home medication is a universal custom, by no means is that meant, but I charge that the practice is sufficiently common to demand very emphatic mention.

Dr. C. I. Kerley, of New York, says: "At the commencement of my junior service on the house staff at the County Branch of the New York Infant Asylum, while making the rounds one day the matter of summer mortality among the infants was being discussed with the resident physician, the late Dr. C. E. Kimball, and on inquiring why so many died situated so favorably as that institution was, and being supplied with good food, pure water and good nurses and competent medical attention, etc. His reply was: 'Take your pencil and write, as we go through the wards, the names of the children I shall indicate.' At the completion of the round, he directed me to keep the list of thirty names, saying that these children probably would not survive the summer. I remarked that these were healthy looking babies; he says they look well, but they have foolish, ignorant mothers; the children have had frequent attacks of indigestion and diarrhea during the winter and spring, the mothers steal food from their own table and give it to the children when the nurses are out of the wards; these children have but little intestinal resistance, and will give us our first fatal cases when hot weather comes.' I kept my list and found that the accuracy of his prediction was startling. But four of the children named, survived the summer."

Now in the second form, entero colitis, we have a continuance and an aggravation of the conditions found in the simple form, and in addition to this there is the added factor of bacterial invasion and infection of the gastrointestinal contents with its attendant inflammatory manifestations accompanied by fever, great restlessness, and persistent wasting of the body tissues, the capacity for food assimilation is very much reduced and may be, for a time, entirely suspended; thirst is great, and there is apt to be vomiting; as a rule there is distended and tender abdomen, considerable griping and pains in the bowels and more or less marked tenesmus.

Prognosis in such cases should be guarded, so much depending on the child's power of recuperation, his resisting power to bacterial

invasion, and his ultimate ability to digest and to assimilate sufficient food to sustain life.

In the third form, cholera infantum or acute gastro-enteric infection, is a form of infection which, while acute in character, is rarely of primary origin, for it is generally preceded by a disordered gastro-enteric digestion. The onset of the urgent symptoms, however, is usually most pronounced, the child being taken suddenly with persistent vomiting and the passing of large watery stools, of a greenish color. The prostration is extreme, the breathing becomes shallow, the eyes sunken, the skin pale in color, the pulse soft and very rapid. The temperature may be very high or it may be sub-normal, the low temperature cases it seems being the most hopeless; the system is so overwhelmed by the infection that the patient is often unable to react, and frequently they die within a few hours after the onset of the attack.

TREATMENT.

In the simple cases stop the milk temporarily and eliminate the irritating gastrointestinal contents, this may be done with castor oil or with medium doses of calomel; to be followed or not, as indications may demand, by some sedative antiseptic; such as bismuth, etc. Stomach washing and enemas may be required in cases that are slow in getting adjusted.

In ileo-colitis you likewise stop the milk, and stop all food for a day or more, then begin by feeding barley or rice water, and resume the milk diet in very much reduced quantities, as the child gains ability to handle it.

Among the drugs, castor oil, calomel and bismuth likewise play an important part in this trouble, as will also some of the malt preparations, and the peptonoids, especially in those persistent cases, and in cases where there is very fetid odor to stools, a combination of the sulpho-carbolites in large doses will be found useful.

Stomach washing and rectal injections are beneficial in that they clear the stomach and lower bowels of mucus and other irritating material and produce quiet and rest.

Opium may be given in cases of great restlessness, just for the purpose of securing a little rest, provided this rest and quiet may not be secured by other and less potent means.

Where cases have reached such low state of vitality so as to have lost all appetite for food, then sometimes feeding by the tube—gavage—for a few days is a life-saving means. Salt baths followed by oil injections may also prove of service in cases of very much reduced vitality.

In cholera infantum, treatment must be directed to the support of the patient. Hypo-

dermic medication offers the best way to counteract the immediate dangers; thus only can we secure the much needed sedation and support. Strophanthus and brandy may be given to sustain; and morphine and atropine, may be used to quiet vomiting, and to diminish the loss of body fluids from the repeated large watery stools.

In the after care of these cases when it has not been necessary to consult the undertaker, and the more violent symptoms having subsided, then must we be most careful in the selection of means to assist the much exhausted system to regain its equilibrium. Plenty of pure water, and pure but very much diluted food, very guardedly given for a time.

NEWS ITEMS AND COMMENTS

FRANKLIN—The Tri-County Medical Society will be the guest of the Simpson County Medical Society July 9th. A fine program is to be given.

GARRARD—Dr. D. F. Smith, of Knox County, Kentucky, has purchased the Lancaster Hospital Building and will practice his profession at this place in the future.

OHIO—Dr. F. B. DeWitt, Rockport, Kentucky, has moved to Utica, Daviess County.

Dr. L. B. Watkins, of Louisiana, has located at Cromwell, Kentucky.

ELLIOTT—Dr. J. L. Lyon, of Sandy Hook, secretary of the Lyon County Medical Society, has moved to Willard, Carter County, where he will continue his practice.

NELSON—Dr. H. E. McKay, of Bardstown, whose health has not been satisfactory for some weeks, has gone to French Lick Springs to try to improve his condition. May he return sound and well.

WARREN—Dr. Lillian H. South, State Bacteriologist, gave an interesting lecture on "Hookworm," at Winchester, before a large audience, on the 25th of last month. She also visited Torrent, in Wolfe county, and gave a similar lecture.

CHRISTIAN—Dr. N. C. McGraw has a new "Flanders 20."

Drs. B. A. Caddle and W. S. Sandbach are the happy owners of a new 20 horse-power, five-passenger Ford, each.

The majority of our physicians are using machines now.

BELL—Drs. W. C. and John F. Evans have their new hospital in Middlesboro fully equip-

ped and are beginning to receive patients.

Dr. McCunley Arthur, of Middlesboro, has been very low with organic heart trouble for the past month but is slowly improving. We wish for him a speedy recovery.

JEFFERSON—Dr. Lewis S. McMurtry, former President of the American Medical Association and one of the most popular physicians in Kentucky, delivered the doctorate oration before the Trustees, Faculties and Graduating Classes of the Medico Chirurgical College of Philadelphia, at its Thirty-Second Annual Commencement, in the American Academy of Music, on Friday, June 7th, last.

WASHINGTON—Dr. W. P. Nichols, who has been engaged in the practice of his profession at Willsburg, Ky., for the past year, has removed to Chaplin, Nelson County.

Dr. W. T. Barnette, who has been practicing several years at Mackville, Ky., has moved to Springfield, where he will continue in the practice of his profession.

BELL—The W. K. Evans Hospital was opened to receive patients the 15th of March, 1912. Graduate nurses only are on duty in the hospital, and Dr. W. K. Evans is Superintendent. The institution contains twenty-four beds, both private and ward. Rates from \$8.00 to \$15.00 per week. The Hospital has its own ambulance and is splendidly equipped in every way, and has more than made its expenses since the opening.

BARREN—Dr. W. S. Blakeman, of Glasgow, one of the oldest and best known doctors in this county, died June 20th, with organic heart trouble. Dr. Blakeman had been a member of his county society for many years and took a keen interest in the development and progress of medical science. A gentleman of the old school, a man honored and respected by his friends and patients, who will be missed and kindly remembered.

WARREN—The many friends among the profession, of J. G. Denhardt, the genial editor of the Times-Journal, will be agreeably surprised to learn that on the evening of June 25th, he was wedded to Miss Eleanor Heriges, of Nashville, Tennessee. Mr. Denhardt has been a regular attendant at the State Meetings and rendered valuable aid in giving proper press notices of their doings. Always obliging and a gentleman, he has deservedly won a kind regard from all of the physicians who personally knew him and we are certain we voice the sentiment of his friends when we wish him through this column, a long and happy voyage on the matrimonial sea.

BULETT—Dr. J. E. Johnson, of Lebanon Junction, died June 19th, with organic heart trouble. Dr. Johnson for many years enjoyed a large and lucrative practice and was engaged actively in his chosen profession until prevented from doing so about two years ago. His son, Dr. Otto E. Johnson, who took up his father's work at Lebanon Junction, is the only one of several children to adopt the medical profession. Dr. Johnson has been a member of his county society since 1906, and will be sorely missed by that body as well as others who knew him.

SIMPSON—Dr. F. C. Bandy, graduate 1912 University of Louisville, has located for the practice of medicine in Franklin, Ky.

Dr. M. M. Moss has moved to Bowling Green, from Franklin, where he will practice a specialty.

Dr. F. E. McCann, who recently located near Franklin, coming from Montana, has been elected secretary of the Simpson County Medical Society.

Dr. N. C. Witt has taken the office of Dr. M. M. Moss in Franklin, since the latter's removal.

FAYETTE—Dr. Julian McClymonds has returned from Europe where he has been doing special work for six months.

The Doctors in Lexington are fast learning the economic value of automobiles and as the result most of them use it altogether with entire satisfaction.

Dr. Jno. A. Wathen read a paper on "Thyroidectomy" before Fayette County Medical Society. Dr. Wathen is a good speaker and presented a difficult subject in a clear and succinct manner that was appreciated by all.

Dr. A. P. Taylor, of Lexington, was seriously injured by his auto turning turtle while returning from a visit to a patient. It was, however, learned later upon examination, that while his injuries are serious they are not necessarily fatal.

The National University of Arts and Sciences of St. Louis, has conferred the honorary degree of Master of Surgery on Dr. A. H. Barkley, of Lexington, Ky.

The Kentucky State Railway Surgeons met in Lexington, May 16-17, and had a very successful meeting. The next meeting will be held in Frankfort, Ky., in 1913. This is one of the five societies in the State.

BARREN—Mrs. G. F. Holloway has returned from Bowling Green, where she had tonsillectomy performed for the relief of parenchymatous tonsillitis.

Richards and daughter, Miss Rachel, of Glasgow, are in Chicago attending

the graduation of their son and brother, Dr. Clifton Richards, in medicine.

Dr. Ewing L. Palmore, of Hiseville, has been appointed as a member of the board of Pension Examiners of Barren County, to fill the vacancy occurring by the resignation of Dr. R. S. Plumlee, who recently moved to Green City, Missouri.

Dr. C. W. Froedges, of Eighty-eight, is the recipient of a ten-pound son, who will some day take his father's lucrative practice.

Miss Flora Redford, a graduate nurse, is visiting her sister, Mrs. Ira D. Turner, of Scottsville, and expects to extend her trip among relatives and friends at Tompkinsville before returning to Louisville.

Dr. and Mrs. R. H. Porter attended the session of the American Medical Association at Atlantic City, and report a splendid time.

BARREN—Dr. R. S. Plumlee and family, of Glasgow, left last month for Green City, Missouri, where the doctor expects to locate for the practice of medicine. Dr. Plumlee was secretary of the Barren County Medical Society for years, always displaying great activity in promoting the interest of his fellow practitioners. We cheerfully recommend him to the Sullivan County Missouri Medical Society, worthy of every token of professional courtesy which may be extended to him in his new location.

Dr. W. F. Boggess and H. N. Lavell will deliver public address by invitation from the Barren County Medical Society. Physicians and their families are urged to attend.

COUNTY SOCIETY REPORTS

Boone—The Boone County Medical Society met at Walton, on May 15, 1912, with the following physicians present: L. C. Hafer, H. H. Hays, O. E. Senour, F. L. Peddicord, B. K. Menefee, J. G. Slater, G. C. Rankin, Merrell Ricketts, G. F. McKim, C. L. Longsdale, and Brown. Prof. Dix, of Burlington, and Attorney Vest, of Walton, were also present.

An old-fashioned fish-fry was enjoyed at the Atlas Hotel.

Merrell Ricketts discussed "Local Anesthesia," which was very interesting, practical and instructive.

F. L. Peddicord then discussed "Trachoma," after which the society adjourned to meet at Union in June.

F. L. PEDDICORD, Secretary.

Boone—The Boone County Medical Society met at Union, on June 19, 1912, as guests of Dr.

Senour, and was called to order at 8 P. M., by President Menefee.

The following doctors were present: Richmond, Slater, Langsdale, Senour, Hays, Menefee, McKim, Hafer, Crisler, Nunnolley, Phinney and Peddicord; also Messrs. Sammons, Malls and Vashell.

O. E. Senour read an interesting paper on "Enterocolitis," which elicited a hearty discussion from **Phinney, Nunnolley, Crisler, Langsdale, Hafer and Menefee.**

C. L. Langsdale read a paper on "Hernia," which was very interesting and ably handled. Discussed by **Crisler, Hafer and Menefee.**

At 10:30 an elaborate lunch was served which was very much enjoyed by all present.

The society then adjourned to meet with Dr. Hays, of Bullittsville, on Wednesday, July 17, at 2 o'clock P. M.

F. L. PEDDICORD, Secretary.

Ballard—We are having monthly meetings this year but owing to bad weather and very bad roads we have had very poor attendance till last month and I am sure now that the monthly meeting will be a success with us.

The society met last on May 2, at La Center, with the following members present: J. D. Hollings, W. A. Ashbrooks, C. E. Harkey, T. M. Baker, J. R. Baker, J. E. Martin, D. E. Burrow, Bob Overly, Prof. C. C. Justice, W. W. Richmond of Clinton, and J. S. Johnson.

Prof. C. C. Justice read a paper on "School Sanitation" which was freely discussed and enjoyed by the society.

W. W. Richmond then talked of preventive medicine, especially hookworm, and distributed mailing cases for specimens. The society became very much interested in hookworm disease and after much discussion and many questions which were answered in an able way by Dr. Richmond, the society adjourned to remain till evening and hear Dr. Richmond lecture on "Hookworm," which was given to the public. This lecture was an exceedingly good one and was very much enjoyed by the large audience that heard Dr. Richmond.

We hope to give more of Ballard county people the opportunity to hear Dr. Richmond in the near future. The people of our county are easily interested in questions pertaining to health and we are anxious to help them.

Bell—The Bell County Medical Society met in Pineville, at the Court House, May 10, 1912. The meeting was called to order by the Vice President, Dr. W. K. Evans, and the following members responded to roll call, Drs. Evans, Foley, Combs, Cornum, Schmitz, Robertson, Brosher, Giannini, Nuckols, Hendren, Haston, Ingram, Bingham, Morehead and Gibson.

The minutes of the previous meeting were read and adopted.

G. T. Cornum presented a clinic, a case of Pellagra.

B. E. Giannini presented two cases of hookworm disease and read a very interesting paper on the subject.

Mason Combs and J. G. Foley, reported interesting clinical cases.

T. T. Gibson read a paper on "Alcoholism."

Both the essayists handled their subjects with skill, bringing out all the essential facts, and both papers were ably discussed by several members of the society.

There being no further business before the society, the meeting adjourned.

O. P. NUCKOLS, Secretary

Barren—The Barren County Medical Society met in Glasgow, June 11, 1912. Members present: White, Acton, Smock, Taylor, Ashury, Ferguson, Porter, Miller, Honaker, Botts, Turner and Jordan.

The meeting was called to order by President Smock. Minutes of last meeting were read and approved.

There being no clinical cases present, **A. E. Ferguson** introduced the subject of "Mucous Colitis," which was interestingly discussed by several members.

R. H. Porter, having attended the meeting of the American Medical Association, at Atlantic City, gave an interesting talk on the work being done by that great body.

The Committee appointed to arrange for our annual social meeting, made its report and was discharged. In accordance with suggestions made by the committee, it was agreed that the meeting be held July 9, that Professors H. N. Leavell and W. F. Boggess, of Louisville, be invited to attend as guests, and deliver popular addresses in the afternoon and evening. Committees were appointed to arrange as far as possible to make the meeting profitable and enjoyable.

J. W. Acton read an excellent paper on Lobar Pneumonia which was discussed by nearly every member present. Opinions differed somewhat on several minor points, but this only made the discussion more interesting.

The Secretary announced the following program for our next or a subsequent meeting—each writer to select his own subject.

1. Paper by **Dr. Ferguson**; discussion by **Dr. Honaker.**

2. Paper by **Dr. Froedge**; discussion by **Dr. Ashury.**

3. Paper on "Pneumonia," by **Dr. Grinstead**; discussion by **Dr. Taylor.**

Adjourned to meet July 9th, at 10 a. m.

J. M. TAYLOR, Secretary.

Barren—The Barren County Medical Society met in Glasgow, May 14, 1912. Members present:

Turner, Miller, Smock, Botts, Acton, Siddens, Palmore, Taylor, Ferguson and Asbury.

President Smock called the meeting to order at 10 A. M.

The Secretary's report of last meeting was read and approved.

There being no clinical cases present, reports of cases were called for.

T. F. Miller reported three cases of "Gonorrhea," which he treated successfully with the gonorrheal vaccine. These were all severe forms, one being gonorrheal rheumatism. In two cases the staphylococcus vaccine was used in combination. The result in each case was a complete success. Dr. Miller sees much in the vaccines to encourage the general practitioner.

C. C. Turner reported a case of "Typhoid Fever," which ran a typical course until convalescence was apparently established, when without any discoverable cause, the patient relapsed, and his condition became critical. The illness was prolonged two weeks, resulting in complete recovery. An interesting discussion followed Dr. Turner's report.

Afternoon.

The committee appointed at last meeting to arrange for our annual social meeting, not being ready to report, were given more time.

A. T. Botts read a paper on "Hec-Colitis," which was appreciated by all present. Dr. Miller agreed mainly with the paper, but suggested the use of warm starch water by injection, and judicious fasting, in connection with the other means mentioned. **Dr. Turner** relies on bismuth more than any other single drug. His experience leads to fear complications and sequelae.

W. F. Asbury relies much on medicines, but more on proper dietary. Condensed milk has been a favorite with him. **E. E. Palmore** agrees mainly with the paper, but prefers symptomatic rather than routine treatment. **J. W. Acton** praised the paper as being thorough and up to date. He believes opiates fill an important place in the treatment of this disease.

Motion carried that Dr. Botts' paper be sent to our JOURNAL for publication.

The chair appointed A. T. Botts to assist in arranging programs for our regular meetings.

The following program was announced for our next meeting:

1. Paper on "Pneumonia," by Dr. Acton.
2. Paper or talk by Dr. Bullock on "Cholera Infantum."
3. Paper on "Sanitation," by Dr. Depp.

W. T. Britt is still held for his paper on "Constipation," as appointed last meeting.

Adjourned to meet June 11, 1912.

J. M. TAYLOR, Secretary.

Carter—The Carter County Medical Society met in regular session at E. K. Junction, May 14, 1912. The quantity was slim, yet of the highest quality and consisted of H. B. Fraley, J. W. Sto-

vall, H. W. Fulkerson and D. B. Wilcox. The President of our society, L. M. Sparks, having gone to Nebraska to locate in a more prosperous field, and G. R. Logan, vice-president, being absent, we elected J. W. Stovall president pro tem.

H. W. Fulkerson kindly tendered us the use of his office which we accepted as a place to hold our meeting and before he could say "seat" we had him on our list as a member and told him the Journal would reach him at Anglin, Ky. Four or five subjects were brought up and given a thorough airing and it was all in all a most enjoyable "meet". Regrets were expressed that G. B. O'Roark and L. M. Sparks were both leaving the State, both having been presiding officer of our society.

D. B. WILCOX, Secretary.

Calloway—The Calloway County Medical Society held its regular monthly meeting Wednesday, June 5th, with the following members present: C. N. Crawford, Linn Grove; R. P. Crawford, Hazel; E. B. Houston, Hazel; C. E. Clayton, Dexter; R. T. Nix, Jones's Mill; B. B. Keys, N. G. Evans, N. H. Mason, P. A. Hart, C. O. Gingles, W. G. Gallimore, R. F. D., S. D. Younte, Murray.

W. W. Richmond, of Clinton, our Councillor, whom we all know and love, met with us and it is useless to say the meeting was very good—our only regret being that on account of sickness in our county just now, more of our members were not able to attend.

The regular program was suspended and Dr. Richmond invited to address the meeting. He gave the society a report of the sanitary measures adopted in the flooded districts of Kentucky from the recent overflow of the Mississippi River, and the results of same. He stressed the importance of sanitation at all times in all conditions of life, and insisted that every doctor present at this meeting go home and preach the "saving gospel" of sanitation and hygiene.

We think the Doctor had this subject on his brain. He lectured on it to the general public the evening before and we thought then he said all that could be said without repetition but when he addressed the society we found he had a lot in reserve.

The rest of the morning session was devoted to discussing the best means to improve the sanitary condition of Calloway county.

Because of the many calls for the doctors it was voted to adjourn and continue the regular program at the next regular meeting.

The Doctor was tendered a vote of thanks and extended a cordial invitation to meet with us not less than once a year.

W. H. GRAVES, Secretary.

Hart—The Hart County Medical Society met in Mumfordsville, May 7th, 1912. Those present were S. F. Richardson, J. J. Mudd, W. W. Bowl-

ing, C. Hall, E. L. Addington and J. J. Adams.

W. W. Bowling had a case before the society, an "Aneurysm of Abdominal Aorta," this case was examined by all present and there were some that differed with the doctor in diagnosis, saying that his patient was a neurasthenic with some gastro-intestinal trouble, etc.

Pellagra, hookworm and some drugs were discussed at some length and all took an active part in the discussions and left feeling that they had been benefited by the meeting.

J. J. ADAMS, Secretary.

McLean—McLean County Medical Society met at Calhoun on June 14th, 1912, with W. P. Miller, vice president, presiding; present: Miller, Thorpe, Moore, Spicer and Haynes.

The following officers were elected: President, J. H. Thorpe; Vice President, W. P. Miller, and Secretary, W. L. Haynes.

J. H. Thorpe reported a very interesting case of "Hypertrophy of the Mammary Glands, in a woman who had borne only one child, now ten years old. The glands have constantly enlarged until they reach below the umbilicus. He thinks, however, that they are being reduced somewhat under the use of large doses of potassium iodide.

The society will be pleased to see reports from other physicians who have had such cases.

On motion the society adjourned to meet July 23, 1912.

W. L. HAYNES, Secretary.

Montgomery—The Montgomery County Medical Society held its regular meeting May 14th, at the office of W. T. Smrall. Present, J. A. Shirley, W. T. Smrall, J. F. Reynolds, D. H. Bush, P. K. McKenna, J. B. Jones.

The article on Fee Splitting, by Dr. C. A. L. Reed, of Cincinnati, Ohio, in *Pearson's Magazine* for April, 1912, was read and endorsed by this society. If there has been any fee splitting in this county there were none present that were aware of it. The President and Secretary were instructed to write to Dr. Reed informing him of the action of this society on said article.

This was our regular meeting for the annual election of officers. At the April meeting a motion was carried to amend Section 3, Article 1, of our by-laws, so as to elect officers at the December meeting instead of May. This amendment had to lay over to the May meeting before it could be voted on; at this meeting it passed without a dissenting vote. So from this time this society will elect its officers at the December meeting.

A motion was carried that the present officers hold over until the December meeting; those officers are J. A. Shirley, President; R. E. May, Vice President; J. B. Jones, Secretary; W. T. Willis, Treasurer; Censors, W. T. Smrall, D. H. Bush, S. E. Spratt; Delegate, C. B. Duerson.

The President and Secretary were instructed to write to our State Senators and Congressmen of this district asking them to support the Cazen Bill for a National Board of Health.

B. M. Mannin, of Spencer, this county, and **J. F. Lockhart**, of Kiddville, Clark county, have located here and we are hopeful that they will soon be members of this society.

Lack of interest in the society with a number of members is our great drawback but we have a faithful few who are rarely absent, but one of these failed to appear at this meeting; he had a good excuse and the same one that the man gave for not being present at the "Great Supper" in Luke 14:20, and we extend congratulations and best wishes for happiness, peace and prosperity to our worthy member, Charles Buford Duerson, and bride, (Miss Nell Herbert Whitfield) who were married in Lexington, April 20th, at the residence of the bride's parents.

J. B. JONES, Secretary.

Lyon—The Lyon County Medical Society met at the office of Dr. Hussey, Edlyville, May 9th, at 2 p. m.

L. P. Molloy, selected at the last meeting for a paper on "Breesh Presentation," being absent, **W. G. Kinsolving** opened the discussion with a very interesting and instructive talk on this very important subject, other members of the society and **W. W. Richmond**, of Clinton, taking part in the discussion, bringing out graphically many complications arising in these cases.

W. W. Richmond, at the Lyric Theatre, at 7:30 p. m., gave a public lecture upon Scatition and Hookworm disease, demonstrating same with stereopticon views. The meeting was largely attended, and every one seemed much impressed with the lecture, and I feel sure its result will be a great benefit to the public.

J. H. HUSSEY, Secretary.

Test for Albumose in the Urine.—Fittigaldi mixes the specimen of urine with six times the amount of alcohol. The next day the alcohol is decanted, the sediment dissolved in as little as possible of a solution of sodium hydroxide (31 to 32 per cent.), and the alkaline solution is tested with the ammoniacal solution of nickel. This reagent is a mixture of equal parts ammonia water and a 5 per cent. solution of nickel sulphate. It is bluish, but when a drop of this reagent is added to the alkaline mixture above, the tint changes to orange in the presence of albumose or peptone. The method can be applied to the blood, first heating to boiling after it has been well mixed with animal charcoal (10 to 20 gm. to 10 or 20 c.c. of blood). The filtrate after cooling is mixed with six times the amount of alcohol as above. This method does not require preliminary removal of the albumin from urine and there is no possibility of confusion with albumin, as the latter never gives the orange reaction.

THE PSYCHOGENESIS OF HYSTERIA.

(AN ADDRESS.)

By CURRAN POPE, Louisville.

In attempting to present to you the subject of the psychogenesis of hysteria, in the very brief time at my disposal, I feel like one who has passed the Laodcean monster and entered the Garden of Hesperides and finds himself beneath trees laden with golden apples. There are so many tempting things—like so many tempting golden apples—that it will be impossible to do more than select from here and there certain interesting features of the psychogenesis of hysteria. In other words, I have a great deal to tell, in a very little time.

In order to understand the pathology of hysteria, it is essential that we should first understand the normal method of thinking. The first drawing which I exhibit is not an original one; it is taken from Starr's old work on "Functional Nervous Diseases," but it serves its purpose very nicely in that it gives us a basis for the understanding of a "concept." A concept is an idea. If we will take the idea of a bell and dissect it mentally, we will find that it is made up of a great many things. It is made up of the sight of the bell, of the touch of the bell, of the sound of the bell; of the various motor and sensory features that go to make up any mental idea of concept. We have auditory and visual memories; word hearing, word seeing, word uttering and word writing memories; various psychic ideas that go to make up the concept of such a simple thing as bell.

Now, starting with this idea, suppose we let the big star in the second drawing represent a "concept." A child, starting in with the concept of bell, gradually builds around the central nucleus; that concept gradually gathers ideas of different kinds of bells and the uses of bells, cow-bells, locomotive bells, and the "tintinnabulation of the bells, bells, bells" as Poe has said. All these additional ideas are generally gathered around it until we have a complex idea; that is to say, the "concept" bell has become the "constellation" bell. Just as astronomers tell us that a collection of stars in the heavens is a constellation, usually with one large central planetary or star body, so it is with an idea; it starts with a concept, around which other ideas are built. The lines on this drawing connected with the central star indicate the various ideas as they collect around the original concept, and is designed to show that they are related to it by many connections, coming from a great many directions in the brain, usually through the association tracts.

We read a great deal about the word "complex" in the neurological and psychological literature of to-day. A complex is not an entity; it is not something that can be felt and measured, but it is, to the psychologist, what "ether" or "atoms" are to the physicist. It is something upon which we may build an hypothesis of mental action. The complex has come to stay with us in neurology and psychology as the basis of ideas. Speaking in very broad terms, a complex is made up of thousands of ideas. But it is not enough for a complex to consist simply of ideas; it must be ideas plus something else and, therefore, it is ideas plus emotions, and these emotions play a great part in the understanding of the

action of a complex and in the appreciation and understanding of hysteria. Now, in order to make my argument a little more illustrative, I will go back to the bell. Taking a simple complex, we might, using a little piece of poetry, put it this way: "The bells-of-Shandon-sound-so-grand-on-the-pleasant-waters-of-the-river-Lea." (Dull-monotonous) but when we put emotion into it, thus: "The bells of Shandon sound so grand, on the pleasant waters of the river Lea," (Intonation) it makes an entirely different impression, both in the spoken time and words as well as in the personal attitude and feeling of the individual.

When we have gathered a certain number of memories into a constellation, or into a complex, with its varying emotions, every new idea that comes in is incorporated into that complex, becomes a part of that complex, and adds to its influence, both attractive and dettractive.

Now then, we will move one step farther, to a higher stage—to a question of personality. Personality is the sum total of the individual. You are yourself and I am myself, and we are alike neither in looks, feelings, actions nor thoughts. Your personality and my personality represent the sum total of our knowledge, of our experience, of our emotions. I have endeavored, in this chart, to put upon paper my idea of how personality is made up. Personality, is essentially mental; that is, speaking in general terms, is essentially mental. Therefore, I have put "mind" in this large outer circle on the chart. This mentality—this mind—has been built up by impressions, by knowledge, that has been brought to it through the muscles, through the skin, through the special senses, through the moral training we have received during our lives, so that when we take the sum total of all of these experiences they represent, in finality, the personality of the individual.

Now, let us pause for a moment and come to the question of hysteria. Hysteria is not the hysteria that is taught, and that is found so much in text-books, save in the symptoms and in the theories. That is a very broad statement to make. I may say, further, that neurasthenia, neuritis and hysteria are the great waste-basket into which ignorance casts its papers. Lasagne, the great French physician, said, "It is the basket for those papers that we do not know where to place."

Gowers has said: "Hysteria is a conception that conceals whatever it covers; we must rescue from it whatever we wish to study."

Says Wilson: "That the domain of hysteria, ranges from insanity to renal disease and from double personality to gangrene is ample evidence for complete reinvestigation."

Hysteria is a disease of the highest level of

the mind, or the psychic level, and the greatest problem presented to the psychologist—not the neurologist—but the greatest problem presented to the psychologist in the treatment and management of hysteria is a thorough and complete understanding of the mechanism of the symptoms themselves, the machinery that is behind the production of the symptoms. It is an easy thing to classify an hysterical paralysis; or, oftentimes, in our endeavors to find anesthesia in an arm, to make an anesthesia, but it is a very difficult proposition to find out what is the mechanism back of the production of that particular symptom, because the symptom originates in the mental machinery of the individual.

I am going to briefly run over four theories of hysteria, three of which we may dismiss cursorily.

First, the physiological theory of Sollier:

Hysteria is a physical, functional disturbance of the brain, consisting in a torpor or a sleep localized or generalized, temporary or permanent of the cerebral centers, and manifesting itself consequently according to the centers affected by vaso-motor or trophic, visceral, sensory and motor and finally psychic disturbances, and, according to its variations, its degree of duration, by transitory crises, permanent stigmata or paroxysmal accidents. Confirmed hysterics are only vigilambulists, whose state of sleep is more or less profound, more or less extensive."

This definition is nothing but a statement of dissociation in physiological terms.

This theory can be dismissed without comment. American medical men, I am sorry to say, are, consciously and unconsciously, prone to adopt this theory of the physiological side of hysteria.

The second is that of Babinski:

Babinski says that it is possible in certain subjects to "reproduce by suggestion, with vigorous exactitude and cause to disappear under the exclusive influence of persuasion, the symptoms of hysteria." That is to say they are produced by suggestion, removed by persuasion. While we owe a debt of gratitude to Babinski for exposing the faulty methods of examination, which can originate hysterical symptoms, still his theory is, in my mind, artificial and does not reach the fundamentals of the condition.

Babinski falls down when he comes to explain the difference between suggestion and persuasion. He says that suggestion is the devil and persuasion is the angel; that suggestion means to influence the individual to accept an idea which offends the reason and is manifestly irrational, but it is persuasion if the idea is reasonable and rational. Incidentally, it may be said that Babinski's theory

is not reasonable and rational nor does it work out in practice.

The third is the biological theory advanced by Sedis and Claporede. The latter accepts Freud's theory (of which I shall speak later); both lay particular stress upon the fact that hysterics show marked resistance to the recall of painful memories, which he considers to be, biologically, a defense reaction. He also believes that sleep is a defense reaction; that we do not sleep because we are exhausted but in order not to be. This latter I am inclined to believe to be true in the main.

Sidis believes that sleep originates from the semi-waking state—the hypnoidal state, out of which may develop on the one hand sleep, and the hypnotic state on the other. He believes that one cannot pass in or out of sleep or hypnosis without passing through the hypnoidal state.

The fourth theory is a purely psychological theory. The theory that is generally accepted to-day is a combination of the work of Janet, of Paris, and Freud, of Vienna, who are very frankly psychological in their beliefs. We will take Janet first. He believes that, underlying the manifestations of hysteria, there is an amnesia, or forgetfulness; that is to say, an absent-mindedness. He says: "Under the stress of some mental shock, or at the bidding of some imperious impulse, the hysterical subject falls into a kind of half faint, or reverie, and loses touch with his surroundings; his voluntary activity comes to a standstill; the amnesia or somnambulism has commenced. He lives the same scene over again, goes through the same actions; he gives himself up to the thralldom of some idea to the exclusion of all others; stimuli from without do not reach him through the ordinary avenues of sense. He is in a dream, living in a little world of his own, which amounts to the sum of the memories and fancies of a particular time-hysterical fancies in his experience." When he awakes, that is, when he becomes conscious, or, in other words, recovers his personality, this much of his personality is shut off from consciousness; that is to say, he has completely forgotten the scene which has just been enacted.

Now, in order to understand and appreciate how an individual can forget what he has been thinking of, we must turn from Janet, who has gone no farther than this, to Freud, who has brought to the scientific world of psychology a new thought. Freud says that psychic determination rules mental life just as much as the physical world is ruled by its laws; that every mental act is just as well determined as the fall of an apple is determined by the law of gravity, and that no one can get away from this fact. He says that the human consciousness—and by consciousness

is meant by the sum total of an individual's receptive condition at any particular time—that the consciousness of an individual must be divided into three levels. First, the level known as "conscious"; that is to say, thoughts of which we are aware, of which we know what is taking place at the time. This forms a very small part of an individual's mental activity. Underlying that is another form of consciousness, which he calls fore-consciousness. In fore-consciousness, the conscious mind can call to its aid all that is stored there; in other words, it is what is commonly known as sub-consciousness, if we want to term it that. The conscious mind can utilize the fore-conscious mind in calling to its aid all of the facts stored in it. But Freud drops one level farther than any other psychologist, and says that, underlying the conscious and fore-conscious is a vast reservoir of which the individual is totally and absolutely unconscious; and out of this "unconscious" he cannot pull ideas; they can only be reached in a roundabout way, as illustrated by the zig-zag lines on the chart; that it is into this unconscious domain that the fancies of which Janet and Freud write so much—it is into this vast unconsciousness that ideas are dropped or pushed.

Now, why should an idea be forced into the unconscious? The only way that we can learn why ideas are forced into the unconscious is to go back to childhood, and many hysterics go back to childhood. The child, when it is born, is in a certain sense unfinished, uncivilized and unpolished. It goes through a course of education, and this education consists essentially of repression; in other words, the child is constantly taught to repress. It is brought up and schooled in the idea, "Don't do this," and "Don't do that," "Don't do this" and "Don't do that" because it is wrong—it is not nice—it is incorrect, so that parents, in teaching children the tenets of civilization are teaching many of them to be hysterics; they are building what Freud calls certain "psychic dams" and "barriers;" they are building up the barriers of loathing, reproach, fear, moral ideas, esthetic ideas, pain, anxiety, sympathy, and injury. Let me make that just a little bit plainer. The child sometimes plays with its feces. The mother immediately corrects it; she reproaches the child; she teaches that child, through fear of punishment, to repress the instinct to act without control; in other words, she teaches that child to repress—to push down—to pull under the instinctive tendencies that are there, and she does that by building up certain moral ideas. "Don't pull your dress up." "Why?" Because it is not moral; it is not nice; it is not esthetic. And so, day by day, these psychic dams and bar-

riers are built up, and the instinctive tendencies, the instinctive desires, the instinctive wishes of the child are crushed down into this unconscious part of the brain and are there stored.

Freud says that hysteria commences when two complexes (you will remember that a complex is an enormous group of ideas, plus emotion) come in conflict. The complex on the one side says, "I want to do this;" the complex on the other side says, "I ought not to do this;" the psychic dams and barriers that have been built up tell him that it is not right to do so. Immediately a conflict arises; a conflict between the good on the one side and the bad on the other. In a good many individuals these opposing forces are equally strong. The subject exercises what he, or she has been taught to exercise—repression, and this idea is repressed into the unconscious. Now, although a conflict has taken place and the idea has been repressed into the unconscious, it has not been killed; it leads an independent existence, is alive, powerful and desirous of coming out, but the "good" sits on the lid and tries to hold it in, and it keeps trying to come out, so that in the end, in hysteria, the two get together and effect a compromise, and Freud's theory is that this is, so to speak, a "compromise with dishonor." In endeavoring to forget, in forcing the idea into the unconscious, and its endeavor to escape, as a result of this conflict a compromise is effected, and we have hysterical symptoms. In other words, then, the hysterical symptom is the result of the conflict between the two complexes, the one trying to get out and the other trying to repress it. Let me illustrate this with a more homely example of a conflict. Let us suppose that a young man is deeply in love with a young lady, but that he has no money and is absolutely dependent upon his father for support. The father is bitterly opposed to the match and opposes it in every way, in an endeavor to compel the young man, if possible, to give it up. One day the young man, sitting, as Janet has said, in a quiet and contemplative frame of mind, pictures to himself what a grand and glorious and beautiful thing it would be to be married, to have his own home, to have his own wife—to have everything just as a *gallant* and his lady would like to have it, and thinking that, if his father would only die, he would get all his money and be able to carry it all out. Suddenly he arouses to the fact that he is actually, mentally, a parricide, wishing for the death of his own father, the man who has brought him into the world, who has nourished him; that he is in reality, in thought, a viper, biting the very breast that has nourished and warmed him. The idea is very hor-

rible to him. Instead of, as a normal individual should, confessing the idea and admitting that it is horrible and he should not have entertained it, he says, "Get thee behind me, Satan," he will not tolerate it, and immediately there arises a conflict between the wish for the death of his father on the one side and the moral repression on the other, with the result that the idea is repressed into the unconscious, and he, or she, develops an hysteria. To put it another way—what has happened? This idea has been driven into the unconscious, and the individual is totally unaware of it; in other words, a part of the individual's personality has literally been split off, just as we would take a knife and split a shaving off a shingle, but at the same time allowing the split-off portion to remain connected at one end with the unconscious, the real idea, and connected at its other end with the hysterical symptom. That is in a crude way Freud's explanation of how an hysterical symptom develops.

The hysterical symptom, then, is a mental creation which takes the place of a disagreeable idea; or, as Freud calls it, a "surrogate creation." But this hysterical symptom is distorted and disfigured; it does not tell you what the idea was. No hysterical symptom will do that. It simply stands there as the representative—as the advance agent, if you please—of what is really hidden in the lower regions of the individual's mind. Freud says that the hysterical patient then gains a certain amount of relief. The conflict is ended; the idea has been repressed. Now the hysterical symptom, if we choose to put it that way, or the complex, may take one of two forms. It may take a physical form. In that shape it is represented by a physical symptom—we will say an hysterical paralysis of the arm. Freud says we then have a "conversion hysteria;" that is to say, the idea hidden in the unconscious of the brain has been "converted" into a physical symptom; in other words, we have a conversion symptom—a conversion hysteria. This gratifies the patient; it satisfies the complex; both of the complexes are satisfied. They have had their altercation, they have agreed upon a compromise and the whole thing is settled; the hysterical symptom represents the final papers in the settlement: both sides are satisfied and both sides are gratified. Now, gentlemen, therein lies the difficulty in getting rid of hysterical symptoms. An hysterical symptom stands for a gratified wish, and the patient does not want to give up the gratified wish because it means a return to the conflict, a return to the old order of things—an order that has been settled and disposed of, and that is the reason why these patients hold so strongly to their hysterical symptoms. We must suppose

that there are certain individuals so constituted that they are subject to physical conversion while there are others so constituted that they are subject to "psychic substitution." If, as a result of the conflict, the idea is not converted into a physical symptom, then we have a substitute for the conflict; in other words, the substitute remains in the mind and does not reach the body, and here we have an explanation of the various phobias and morbid dreads, of so-called psychasthenic conditions, of the "compulsion neurosis." Therefore, when the splitting-off, or dissociation of personality takes place, it may occur in one of two ways, either as a conversion into *physical symptoms*, or as a *psychic substitution* into morbid fears, or morbid dreads; it may be simply an intense morbid depression.

Now, how are we going to reach something that the patient cannot tell us anything about? These individuals are unable to tell us one single thing about the conflict; how it originated, or that there was any conflict. If you were to know it and mention it to them they might absolutely deny it. We will have to go back again to the explanation we had of a complex. The hidden complex in the unconscious has strings attached to it. The ideas that are so devious and disagreeable in character have little strings connecting them in a roundabout way with the fore-conscious, and we must by psychological methods pick up these little golden threads and follow them, just as the King followed the golden thread in the mazes of Hampton Court to his lady love hidden in the center, so the psychologist of to-day picks up the thread that leads by devious ways, into the unconscious to find out the origin of these morbid fears and hysterical symptoms. We can often reach the unconscious by what is known as the "association test." Words often stand for actions, and thus, by reading out say a list of 100 words, to a patient, one at a time and allowing him to answer to each, the first words that come into his mind and timing the answers with a stop-watch, we can often times gain very valuable data which will pull us on the rail. One of the most valuable ways of reaching the unconscious is through "dreams." Dreams tell us, in symbolism and in allegory what is hidden in the unconscious. When the conscious and the fore-conscious drift off into sleep, the unconscious has its inning—it comes to the bat; and, while even in sleep, the least cannot come out in the shape in which they originated, they may come out in allegory and in symbolism, and he who can read allegory and symbolism of dreams will, in little while, be able to trace the idea which originally gave rise to the physical symptoms of psychic substitution.

Or, we may subject the patient to psychoanalysis; that is to say, we may subject the patient to open, free association, having him talk and tell us everything that comes into his mind, letting his mind drift hither and thither, here and there, in a zig-zag, unconscious sort of way. In this roundabout way at times directed by the physician, we will be able to reach the underlying idea that is causing the trouble.

The subject that I have brought before you to-night is, in my humble opinion, one of the most significant contributions to medicine and psychology that the world has ever known in many years. Freud has met with the most violent opposition. Everybody does. Pasteur, with his fermentative bacteria, had the whole scientific world on his shoulders; Lister was divided, and what is he to-day? It is nothing new. Freud has been doing this work for fifteen years or longer, and to-day it is reaching out to the psychology of every act, every deed, of the human race, and it has been actually applied in the following. Hysteria, anxiety neurosis, compulsion neurosis, psycho-neurosis in general; the psychology of every day life etc., why we forget, why we like this and like that—all things of every-day life that are not really pathological.

In the last *Journal of the A. M. A.*, Bailey and somebody else brings the psychology of Freud to bear on the rhythmic movements of idiots and imbeciles. It is to-day accepted by the very best men in this country—such good thinkers as Jones, of Toronto; Putnam, of Boston; Brill, of New York; Stanley Hall, in part by Morton Prince and I might add by many psychologists all over the country. They generally accept the following:

First, determinism, that all acts are psychically determined.

Second, that there are such things as psychic-conflicts, and psychic trauma, and that the symptoms and causation of the various phenomena are the result of repression.

The questions of conversion and substitution are, of course, natural correlaries of the others; if one accepts the foregoing, he must also accept the aftercoming.

I have treated a number of patients by this method in the past three or four years, and I have had the good fortune to have secured some most interesting and satisfactory results. If the complex can be reached, abolished or satisfied, the morbid manifestations of that complex will cease. Psycho-neurotic, neurotic, and hysterical symptoms can be all avoided if we can but convince the personality of the patient that he was wrong in resisting the pathological wish; in other words, if this young man could have been made to realize that there was a pathological wish but that everybody has that kind of wishes, and

that a normal, strong, healthy man admits them, faces them and conquers them—if we can make him admit the repressed idea, we can in this way get rid of the trouble. When we have found out what is back of the symptoms, we can make the patient take up the conflict and fight it out, rise to sublime heights and overcome it; or make him strive to follow out his life in a better way; or, we can put him through a process of mental re-education, and that is what a great many of these cases require.

From my own personal observation, and from study of the methods of Janet and Freud, I have come to the conclusion that the average individual, when he first studies the various methods and work of Freud, is apt to cast them aside as altogether wrong and improbable. I did it myself. If, however, one conscientiously tries the methods, he will keep on trying, and find therein satisfying experience and explanations of mental and physical symptoms that were to him inexplicable, puzzling, incomprehensible. The study is a profound one and is at first puzzling and difficult to understand. All of Freud's works and writings are most difficult books to master. There is not, in English, one good text-book on this subject for the student or practitioner, and very little general progress will be made until this is had. The Freudian psychology has a special and peculiar nomenclature of its own, most of which is difficult of comprehension, and which I have endeavored to eliminate to-night. The fundamental principles, accepted to-day, are, determinism, conflict, repression, mechanism of the causation of symptoms. The treatment of these cases is in reality a specialty of itself, or a specialty within a specialty. Freud's theories have now reached a point where they must be subjected to investigation in an absolutely impartial manner by the profession, and the truth, in whole or in part, determined. The time has come, gentlemen, when we must emancipate ourselves from prejudice, from the feeling that we must reject something because we do not know what it is. The day has long since passed when a medical man should be willing to admit to himself that he would oppose anything because he did not know about it. The time has come when we must be broad-minded and liberal enough to realize that while in one man's life-time he may be able to see many things and do many things, yet he masters only one thing; he who works must be content to be worker in one field and a receptor in others. At the start, my position in this matter, I am sorry to say, was a false one. I rejected it, but was induced through personal persuasion to take it up and work with it, and I have become thoroughly

converted to the facts. They are called *theories* but in reality they are *facts*. In reviewing my own experience, and from the talks I have had with others, I feel to-night that my position in this as well as in many other things, will hereafter be, that of Hamlet, on the platform at Elinore, when he said to the ghost, "Go on, I will follow thee."

DISCUSSION.

Jno. J. Moren: Dr. Pope has given us a very good talk on a very interesting and a very important subject. There is no doubt in the world but that we are very materially influenced by the impressions gathered in early life. I have seen this demonstrated in a number of instances in my own practice, and I am thoroughly satisfied in my own mind that many things occur that lead to the development of the various psychoses, morbid fears, etc. Dr. Pope has, I think, given a very excellent explanation of Freud's theory. The only point upon which I would take issue with him is upon the question of hysteria. There is no doubt that many psychoses, so-called psychasthenia, morbid anxiety, anxiety neurosis and morbid fears, may be explained by the theory which the doctor has expounded, but I cannot concede that this explanation fits all the cases of hysteria that we meet with in daily practice. I cannot get rid of the old idea of heredity in connection with hysteria. The longer I practice and the more cases of hysteria I see, the more firmly I become convinced that its basis, the groundwork on which it is constructed, is in the original make-up of the individual. Why is it that two, three, or four individuals belonging to one family will develop classical symptoms of hysteria? Can you explain that except upon the individual characteristics of that family. The doctor speaks of "personality" and "emotions". In my opinion, hysteria hinges upon mental disturbance dependent upon an hereditary defect. Various emotions may bring it out, but they are the exciting causes and not the principal factors.

I think all these points should be considered before we accept this theory as the explanation of all cases of hysteria.

C. H. Harris: It would be a very hard matter for an ordinary practitioner to add anything to the splendid talk that Dr. Pope has given us. I wish to simply relate a case that I saw with the doctor a year or two ago.

I was called to see a woman who had the most pronounced hysterical symptoms I have ever seen. Her muscles would contract in such violent tonic spasms that I was apprehensive that she would break her bones. After exhausting every measure that I knew anything about, or that Dr. Weidner knew anything about, and being unable to afford any relief whatever, I called in Dr. Pope. I had been unable to analyze the cause of her trouble, and it remained for Dr. Pope to get at the bottom of it and cure that woman in a very

short time, and I am going to try to tell you how he proceeded to do it.

It had happened that this woman had visited a summer resort some months previous to this attack, and while she was at dinner one day, a woman dropped dead at the same table. She denied that this incident had anything whatever to do with her trouble. Her denial had been sufficient for me, especially as she gave a history of certain nervous symptoms previous to this incident, although the pronounced symptoms had not become manifest until some five or six weeks after the occurrence. When I called in Dr. Pope, he immediately began to analyze the mental workings of this woman. By the time he had completed this analysis, he had obtained from this woman a minute description of the woman who had fallen dead at her table; the minutiae of her dress, the peculiarities of her physique, the color of her eyes, the color of her waist, the material it was made of, the kind of shoes and stockings she had on, the peculiar circumstances surrounding the meal.

He took a long list of jumbled-up words, and instructed the woman that, when he read a word, she was to answer with the first word that came into her mind, and he timed her answers with a stop-watch. When he said, "Day", she instantly answered, "Night"; when he said, "Warm," she replied, "Cold". When he came to "Eyes," she hesitated a moment and said "Blue". He went on this way through a long series of words, and when he had finished he had a complete picture of the incident just as it was pictured in this woman's mind.

It seems wonderful to me how these things had been pushed into the subconscious mind and yet how quickly they were brought out and made to show a picture of the cause of that woman's hysteria. What he did to relieve her, I do not know, but he certainly made a most beautiful analysis and splendid results followed.

Hugh N. Leavell: I think we have all been very much interested in the subject that Dr. Pope has brought before us to-night. If we as doctors would pay a little more attention to the psychology of our patients we would have much less trouble with Christian "Scientists," and all sorts of isms that are constantly cropping out. There can be no question that all these things originate from some concept of a diseased mind, and if we as physicians can, by proper instruction, guide our patients away from such concepts, we will do a great deal towards building them up. The administration of drugs is not the whole province of the medical profession. We have a certain amount of personality and there are things that we should impress upon the minds of our patients, which we cannot do by prescribing drugs. If we will study our patients a little more and throw into the practice of medicine a little psychology, I think we will make much better doctors.

Bernard J. O'Connor: I have read a great deal about Freud's theory by various authorities, and I must confess that the more I read the more puzzled I became. I tried to follow this reasoning, because I had several patients on hand in whom I thought possibly the application of his theory would do some good. It seems to be a rather difficult matter to elicit a repressed concept and I fear that I made the mistake of trying to bring out the repressed thought in a too direct fashion, endeavoring to elicit a history of some painful impression that the patient had received, which had brought about a conflict, resulting in the idea being repressed into the unconscious, where the whole pathology of the condition lies. I did not attempt psychic analysis by means of a series of words read to the patient. That is a method, however, in which I presume one could acquire a certain degree of skill after considerable practice. I think this method has also been employed as a sort of "third degree" test in certain criminal cases, as an aid in the detection of crime.

To my mind, in major psychoses, the main point is to determine whether we are dealing with a true psychosis or insanity. To do this, of course, requires a broad experience.

Another point which interests me is the possibility of detecting ideas which have been repressed into the unconscious through the medium of dreams, as mentioned by the essayists. This opens up a very large field. I feel that we are all indebted to the doctor and I hope that we will soon be supplied with a text-book which will enable us to review the whole subject in such a manner as to give us a definite working knowledge of it.

I would like for Dr. Pope to tell us in closing whether, in his opinion, parents should endeavor to not inculcate in children the idea of "Don't do this" and "Don't do that"; in other words, such ideas as will tend to the production of the "psychic dams and barriers" he spoke of. My own opinion is that when a child is told not to do a thing, he or she, should be told the reason why they should not do it. In many instances, parents will reprove or punish their children without giving them any reason for it, and I do not think this is a good plan.

There is just one other point upon which I would like for Dr. Pope to give us some information. Many authorities who have written on this subject seem to think that Freud's theory is based almost entirely upon sexual abnormalities; that it is mainly in connection with sexual subjects that "conflict" and "repression" takes place. In the paper and discussion here to-night, not a word has been said along this line, and I hope that Dr. Pope will mention it in closing.

Curran Pope, (Closing): I very much appreciate the kind remarks that have been made, and I will try to answer in detail some of the ques-

tions asked, commencing with my good friend, Dr. Moren.

Evidently Dr. Moren did not grasp the statement I made, and which I said that I accepted; that underlying all these cases of neurosis, there is a certain something—shall we call it heredity or shall we call it hereditary predisposition. Call it what you will, it will make of one individual a conversion hysteric and of another a psychic substitution individual. What this is, Freud nor any one else has as yet been able to offer an explanation, except that Freud throws out the idea that in 50 percent of these cases there is a specific heredity. That is all he says—nothing more.

Now, in regard to three or four individuals in the same family having hysteria. I am sorry that Dr. Moren is not here, because I want to take flat-footed, unqualified issue with every word he said. Let us take, for example, an individual family in which three or four cases of hysteria have developed. You will find that these children have all been born of the same parents; they have lived with the same parents; they have all experienced the same petty troubles and conflicts in the household; they have had to stand the cholericness of Pa and the pettishness of Ma; in other words, they have all four lived in the same environment, acting and counteracting upon one another battle-dore and shuttle-cock, until sometimes the wonder is, not that we find three or four cases of hysteria in the same family, but that anybody escapes, including the cook. In an extended career I have seen families in which it was, to me, a marvel that any of them escaped hysteria. I know of one in which, of five children, two have had anxiety hysteria, another has had hysteria; the fourth has had a psychasthenic psychosis, while the fifth—the oldest boy—is absolutely normal. I take it that this boy laid the foundation for his life prior to his eighth year, which was the turning point in that family. He had the advantage of his parents being in good health, and in better financial circumstances, and his early environment contained none of the elements which go to form the foundation for hysterical symptoms, but the others who came after him, all experienced the same environment and the same influences, and the little imitative monkeys (of that is what all children are) absorbed every bit of that environment to the fullest extent, and the wonder is not that these four children developed hysterical symptoms, but that the boy remained absolutely untarnished.

I wish to take very great exception to another statement made by Dr. Moren. We cannot inherit emotions; they are of our individual manufacture. We may inherit certain traits. I may inherit from my father an ability to speak, or rather a connative hereditary trend in that direction, but my father did not put emotions into me. I make and manufacture my own emotions, and these emotions are based upon every complex that I have gathered during my life-time. Dr.

Moren has failed to grasp clearly the psychology of the condition. That is the reason why I am sorry for any man to be absent when I make such a statement. He is all wrong in his idea. You are your own personality. I have stated that a number of times here to-night. Your personality is made up of the sum of your experiences, sensations and emotions. Therefore, you cannot inherit them. You may inherit a certain connative tendency towards the expression of emotions, but you cannot inherit emotions; they are your own.

To my good friend, Dr. Harris, I extend many, many thanks for his eulogies, both personal and professional. I am happy to say that, in the case he referred to the association test, gave much valuable information as to instantly put one on the main track instead of sidetracking him as is sometimes the case. It enabled one to penetrate pretty promptly into the unconscious of that patient. There was no question but that the experience mentioned by Dr. Harris was the essential cause of the attacks, but it was not all; it was connected, link by link, with a number of experiences, one of which dated as far back as ten or eleven years, and which came out in the course of the analysis.

A Voice: Why was that experience such a skeleton that she should wish to hide it?

Curran Pope: I cannot tell you that without revealing a certain incident in the family history that I would rather not tell in public, but the reason it affected her so strongly was because she unconsciously so intimately associated it with her own story that the incident carried with it an emotional value far beyond what it would ordinarily have been. That is what I wanted to call particular attention to. Sometimes we wonder why it is that a patient will develop an hysterical paralysis of the left arm, for instance. Let us say that a mother is nursing her child. She is worn out; the strain has been very great. She is, we will say, on the verge of hysteria. She drops into the trance-like state described by Janet and Freud. She has her left arm hanging over the chair, and, in common parlance, it "goes to sleep." As she comes out of the trance she, as Janet says, forgets the left arm; in other words, she has an hysterical paralysis of the left arm. It was not the trance that caused it; it was the idea she had in her mind. The paralysis is merely the surrogate creation—the outside symptom of what was in her mind while she was in the trance-like state.

I am glad that Dr. Leavell brought up the question of Christian Science, which is neither Christian nor scientific in any sense of the word (applause), and it is fast going to pieces in the absence of the master mind of that keen old business woman and hysteric, Mrs. Eddy, who started out with an hysterical monoplegia and ran the whole gamut, and who robbed old Phineas C. Quigley, in an audacious and outlandish manner

of what is now called Christian Science, which is to-day filling the world with hysterics, for Christian Science says, "Throw out the conflict, repress the symptoms; you haven't got them; forget them," thus doing the very thing that, as all psychologists know, works the greatest amount of harm. "Blessed be the meek in spirit."

I will answer Dr. O'Connor's inquiry in this way. The doctor could not translate for me a sentence in Sanskrit, nor in ancient Greek or Egyptian, because he knows none of those languages. By the same token, he might just as well have asked his patient to write or talk to him in Sanskrit. There is an old saying that "What you don't know don't trouble you." That is not true now; it is what you don't know that does trouble you. An important point in hysteria and other psychoses is that the patient does not know anything about it, and when you question them about it they deny it. You have to "whip the devil around a stump" and make them bring it out. You do not bring it out as you would a catalytic ferment; you take a part in the process but you are not all of it; you are merely the master mind, the guiding hand, and the patient does the rest. The patient oftentimes does it unconsciously; it comes out fragment by fragment, and it requires the widest reading, the broadest comprehension of humanity in general, the most minute knowledge of folk-lore and mythology, to enable one to read, in symbolism and in allegory, many things that would mean nothing to another. It is astonishing how the mind of the modern individual, who knows nothing of Greek or mythology, will yet work along the line of mythology and folk-lore, often going back to the cave-dwelling days of our ancestors. The development of a boy, his growth from a child to a man, represents, in its various stages, the growth of the human race. We see him at different times, with his knife, with his bow and arrow, with his sling and stone; he goes through the various ages through which the human race has gone, and oftentimes he uses symbolism to express various things of which he has no literal knowledge of their meaning. Therefore, what these patients tell us we must be able to interpret, just as we would translate a sentence in French or in German into English.

The association test has been widely employed. I use it constantly as a means of measuring the amount of knowledge in children, and in mental tests of individuals who are suing for damages, etc. Dr. Haymond will recall a very interesting case that we worked out together recently in a young man from Missouri, in whom we were able, by various tests, to establish the existence of mental lesions which absolutely indicated certain defects in intelligence and memory. The association test was used during the trials of Meyer, Haymond and Pettibone, in Iowa, thousands of words being used in the tests.

Dreams are very valuable as a means of reach-

ing the repressed ideas in these cases, but dreams must be read in allegory and in symbolism; the idea never comes out directly. To go back to my previous illustration, the young man does not dream that he wishes his father were dead, but he will relate, for instance, a dream something like this: "I dreamed last night that I saw Mr. X (who, we will say, bears a strong physical resemblance to the father) and Mr. Y, (who exhibits mental traits which the patient thinks resembles those of his father) being carried along in two caskets, the caskets being escorted by a band, which was playing some lively air, totally inappropriate to a funeral." Now, when one comes to analyze that dream, he is apt to find that in the two corpses the patient has combined the mental characteristics and physical appearance of his father, and the dream had its origin in the thought which has been entertained by the patient, of what a good time he would have if his father were dead. This illustration will serve in a crude way, to give you an idea how a dream may, in a roundabout way, express the thought which the patient has entertained and repressed into the unconscious.

A certain amount of intelligence on the part of the patient is absolutely necessary to do this work. We must select our patients. I recently received a very hard jolt and fell down sadly in a case in which I attempted something that I should have known better than to attempt. I attempted to make a silk purse out of a sow's ear, and nobody ever did that nor ever will. I endeavored to work with a patient whose mentality was not up to the standard required, and I failed in a dismal sort of way. The individual must have a certain degree of intelligence, and must be with you in the work. They must give up, to a certain extent, their personality, and tell you their thoughts and ideas as they come into their mind, without attempting to change them, without attempting to criticize them, without attempting to reason about them; in other words, the patient must be as passive as possible sit in the chair, lie back, and talk. One of the best subjects I ever had was a little girl, seven years of age, whom I relieved of a phobia of three and one-half year's duration, which had practically driven the child to desperation. I have never in my life seen, in a child, such intelligence, such beautiful language and symbolism, as this child displayed. There was a child of rare intelligence and rare comprehension, in whom my efforts were rewarded with absolute success. On the other hand, the woman, 21 or 22 years of age, was a tank failure, and the fault was mine—not her's. I tried the impossible, and gentlemen, you know that when an irresistible force meets an immovable object, there is bound to be a smashup somewhere, and that is what I hit.

Dr. O'Connor has asked about the sexual aspect of Freud's theory. Freud's work is all based upon sexuality of the individual, but I purposely

avoided that phase of it in bringing this subject before you to-night, and I will tell you why. The great trouble in bringing that phase up at the start is that the average man and woman cannot separate sexuality and sensuality; the moment you mention sexuality they imagine that it has to do with the sexual act. Some of the most sublime qualities exhibited by human beings are born of sexuality. The love of an animal for her young is an evidence of sublimated sexuality. The devoted love of a mother for her sick child possesses no trace of sensuality—but it is sexuality. There is no question in the world but that Freud is right; that even in its earliest infancy, from 3-12 years up, the child begins to take up sexual subjects, and to become cognizant of sexual matters. In the case of the child I mentioned, 7 years old, her trouble originated in sexual trauma—mental, not physical. There is no question that the sudden awakening of a child to a knowledge of its sex is often the starting point, and that oftentimes the complex producing the hysteria is connected with other ideas, deeper down in the mind, that have to do with sexuality, and when you come to analyze why this is so, you will most likely find that the psychic dams and barriers were nearly all associated with sexuality, or with those things that are closely allied to sexuality.

Now, get this firmly in your mind; don't forget it; take it home with you and keep it so that none of you will be mistaken. Nearly every one of the individuals afflicted with these psychoses, especially women, are sexually anesthetic. If you ask them about it, they will deny it. They will deny it because those psychic dams and barriers which have been erected have been repressed into the unconscious, and they know nothing about them. If you broach the subject to them, they are insulted. They have forgotten about their sexuality; it has been repressed into the unconscious and is now only active in a pathological sense. For one to broach such a subject to them would stamp him, in their eyes, as being an ignoramus of purest ray serene.

There is nothing in the world that will tax your knowledge, patience, tact and ingenuity, nor that will bring out the broad, humanizing side of your nature, as much as will this work. Four years study of this work will come nearer to making you truthful to yourself than almost anything else in the study of medicine. It has a broadening, humanizing effect upon the worker; it makes him know his patients as he has never known them before; it makes them better and it makes him a better man.

As to the mode of analysis, I do not think there is any regular method of procedure. We have no way of knowing what our patients can and cannot do. Usually we start with the association test and that will show us whether or not it is worth while to go further with that particular patient. Dr. Van Zandt will recall a case that

I examined for him, in which, after making the association test, I advised that it be given up, as the patient was absolutely hopeless and beyond redemption so far as psychological methods were concerned. One advantage of the association test is to give us an insight into the type of mentality of the patient, but sometimes it tells us nothing, in which event it is dropped. If the patient is a pretty good dreamer, I prefer to work through dreams. I am much more familiar with dream psychology—with mythology, folk-lore and symbolism, which enables one to interpret dreams—than with anything else, and for that reason naturally I prefer it. Take a dream of the type I cited. We begin with Mr. X, and let the patient tell all he or she knows about Mr. X.; that he lived at such-and-such a place, and by-and-by, that he looked a good deal like the father, physically. There is the gist of it, and we must know it when we come to it. The patient may be going straight along, and you must nail each fact as it comes out; if you miss it, it is gone. It is very fatiguing work and requires an immense amount of concentration. Then we analyze Mr. Y., and we find that his mental characteristics resembled those of the father, and when we combine the physical appearance of Mr. X with the mental characteristics of Mr. Y., we have an individual that would closely resemble the father in every respect. There you have it. Then we take up the fact that the hand was playing a lively air, for instance, "A Hot Time in the Old Town To-Night." The patient will begin—"I remember the first time I heard that song," and so on with a string of nothings, but after a while he, or she, will say—"Every time I hear that song it makes me feel fine." That is the real thing—old man dead, joyful song, feeling fine. It is not something that you can find out easily; it is going to require ingenuity, knowledge and tact to bring out these things. That is why I said it is a specialty within a specialty, and unless a man is specially equipped for the work, unless he makes a constant every-day study of it, he is going to find—as Dr. O'Connor stated, and as I found—that it is one of the deepest, most profound and most confusing subjects that has ever been presented to the medical profession, and I believe that it is destined to revolutionize the entire psychology of the world as it is to-day. In an article recently published in the Journal of Educational Psychology, it was stated that the man who has to deal in a psychological way with human beings, who did not at least understand the fundamental points of Freud's psychology, should not be deemed capable of dealing with a sick individual.

I have personally, to-night, tried to steer away from the technical terms used by Freud, which have a great deal of meaning to those who understand them. It is a subject in which I am profoundly interested, and by means of which I have obtained some most gratifying results. I

think the time is coming when the family physician must know the origin of these conditions, and how to have them treated, and just as when he diagnosed abdominal lesions he calls in a surgeon to operate, so he should be able to recognize these conditions in order that he may more intelligently understand his patients and, as I stated, understand his own limitations.

PRURITIS FROM A MEDICAL AND SURGICAL STANDPOINT.

By M. L. RAVITCH, Louisville.

Pruritis is a functional disease of the skin characterized solely by causation of itching with or unaccompanied by the organic changes of the skin. Itching is a sensation which is not closely definable in words, and which, produced by an irritation of the papilla of the skin, but differing from the sensation of burning, tickling or pain, causes an irresistible inclination to scratch. It exists in all degrees of severity and frequently proves a source of great distress. Some cases are very severe. The day and sleepless nights are passed with intense suffering until the patient is thoroughly exhausted and often unable to move around. It occurs in all stages of life. The itching may be constant or intermittent, and being invariably worse at night. It may be local or general but seldom involves large portions of the surface at once.

Pruritis without any eruption is not strictly a skin disease. In this short paper we will not dwell strictly on the itching due to skin diseases but to some other constitutional causes. Should I attempt to enumerate all the causes of pruritis I would have to write a voluminous essay, and not wishing to punish you, I will just make a few passing remarks.

It is right to mention that often no satisfactory explanation can be obtained, as the cause which produced it may have disappeared, while the itching continues, owing to entangled nerves or filaments having, so to speak, contracted a bad habit. Occasionally the disease is mental rather than physical.

The diagnosis of pruritis is easy: in fact, the patient furnishes us with it; but the diagnosis of the cause which is more important, is often obscure. I will attempt to give a few diseases that are likely to be connected with pruritis. Often have we seen intense pruritis in genito-urinary diseases. I recall a case of intense itching in the vagina, which the general practitioner passed off as insignificant nervous trouble. A vaginal examination was never made by him. When the patient was seen by me, I advised her to consult a gynecologist; the latter discovered uterine

polypi. After the polypi were removed the pruritis entirely disappeared.

Pruritis of the vulva may be at times, purely of nervous origin, but it is always well to look into the history of the case. Most of the cases of true pruritis of the vagina are in women who are passing through and have passed through climacteric period. Some cases of pruritis may start from a slight abrasion due to mechanical injury. This is also true of pruritis ani.

Pruritis vulvae and scroti, if not corrected at once, may, particularly in the young, lead to pernicious practices, such as masturbation. It starts with a pleasurable relief often obtained from scratching. Many cases of masturbation have their origin in pruritis.

In another case, a male patient complained of intense itching about the genitals. A cancerous prostate was found to be the cause of pruritis. I recollect a case of intense itching over the abdominal area, at times accompanied by urticaria. The patient was a man about 50 years of age. The case looked suspicious. Pain over the abdominal region began to appear quite often. Cancer of the gut was the real cause.

A young man came to my office complaining of an intense itching over the body above the umbilicus. His skin was yellowish and very dry. Some places looked like scleroderma. Urine did not reveal anything abnormal. Calculi in the gall bladder was the cause. When the calculi were removed by an operation, pruritis disappeared, and the skin became normal. The dry patches (scleroderma) have also disappeared. I could cite many cases of the same nature, but that would take up too much of your time.

It is needless to call your attention to pruritis due to external irritants, constipation and ptomaine poisoning. You are all acquainted with such cases. Undoubtedly a pruritis due to these conditions is produced by a toxin.

Pruritis of the urethra is in the majority of cases, due to gonorrhea and to the excretions produced in the urethra by the gonotoxin. Pharyngitis may produce a severe pruritis accompanied by erythematous patches on the skin around the neck and shoulders. This latter manifestation is due to a toxic condition produced by the bacilli of influenza.

Any otologist will tell you that otitis media in children as well as in adults, is accompanied by pruritis in the ear. You have all seen the picture of an infant suffering from otitis media try to scratch the back of the ear when there is not a sign of an eruption.

Mastoiditis is another cause of pruritis; so is conjunctivitis.

Serum injections sometimes produce a severe pruritis, at times accompanied by vio-

lent urticaria. Pruritus of this kind is very persistent and is due to anaphylaxis. Ingestion of food proteins such as tomatoes, berries, crabs and the like, is liable to cause intense pruritus with or without urticaria. This is, to my mind, a manifestation of the individual against a particular protein. Rose and Hay fever may often cause pruritus. This condition, as in the ingestion of food proteins, is also due to anaphylaxis. Hirshberg was right when he made the statement that "the recognition of the offending protein, whether its invasion is per os or by injection, whether it is via the olfactory route or by way of circulation direct, is of such clinical importance that internists dare not longer ignore the application of our knowledge of anaphylaxis." In burns that looked for a time very favorable, and then, all at once prove fatal, pruritus usually starts when a burn begins to take on a bad turn. This is also due to anaphylaxis. Anaphylaxis is induced by absorption of substances from the burned tissues which act like an antigen; after a certain time the body becomes sensitized and any further absorption entails fatal anaphylaxis phenomena. Hence the importance of removing all the burned tissue in the beginning.

Gastric hyperacidity produces pruritus. Sometimes acidity is liable to do the same.

Morphinism is another cause of pruritus. I remember a patient came to my office for an intense itching all over the body. At times erythematous nodules were seen on the upper and lower extremities. The case was rather puzzling. As the patient was a prominent lady, very intelligent and ambitious, I did not suspect anything at the beginning. I took the case to be obscure in its etiology. Later I noticed pinkhead punctata over a few nodules and my suspicion was aroused at once. I knew I had to deal with a clever morphine subject. Sound advice and talks did not help the patient; a year later she committed suicide.

Pruritus of the external genital organs in a woman is of a sympathetic or of local origin. It is produced by an irritation of the uterus, bladder, rectum or vagina; or by acid discharge, upthae, or other causes of local irritation of the vagina and vulva.

In the early part of pregnancy, pruritus is very prominent; sometimes it has been the cause of miscarriage. Gynecologists will tell you that cirrhosis of the uterus often causes pruritus of the vulva. So does glycosuria. Varicose veins of the rectum and the vagina give rise to pruritus of the vulva. Varicose veins of the labia cause pruritus of the vagina, pubes and rectum. Pruritus is also occasioned by local causes: about the rectum, by ascariides, piles and fissures; about the upper lip, by nasal discharges; about the ear,

by disease of the middle ear, which later terminates in eczema. Intestinal parasites, diabetes, cystitis, leucorrhea and gonorrhea, and Bright's disease are all well known factors in the causation of pruritus.

Pruritus due to hepatic disorders is accompanied and often unaccompanied by urticaria, jaundice and some kind of skin eruption. According to Murcheson, and other authorities, the exact manner in which the disorders of the liver affected the skin, has never been demonstrated, but it could be readily understood that a toxemia from an imperfect liver action might irritate the nerves and cells of the skin, and in conjunction with external causes or independently, could give rise to pruritic sensations and alterations of structure, as it could cause changes in the joints in gout and deforming arthritis.

Pruritus due to renal derangements is a more satisfactory field for observation and research, than due to liver derangements, because of the ease with which urinary excretions could be secured and analyzed; their relations noted and cause obtained. The urine is the most perfect exponent of the catabolism and anabolism of the system.

Pruritus around the anus is not only distressing but also embarrassing. It especially occurs among people who frequently appear in public. The desire to scratch these parts when involved often becomes irresistible. Public speakers, lawyers, clergymen, singers, and even judges on the bench, if affected, may be driven, in the midst of their duties, to retire and scratch or rub the parts.

Pruritus is occasionally of special type: It may be specially localized, and the condition known as *formication*. This, however, belongs to *paraesthesia* kind.

Pruritus is the result of various atrophic changes which take place in the senile skin. It is due to wasting and ultimate disappearance of the papillae. The same condition is found in extensive burns.

Pruritus biennialis, or *aestatis*, is a neurosis and according to Diakonoff, consist primarily in abnormal irritation of the cutaneous sensory nerves, which, in the reflex way through sympathetic ganglia and vaso-motor nerves, brings about a localized paralytic dilatation of the cutaneous capillaries with a subsequent disturbance in the nutrition of the sensory nerves. As I said before, the disease is often mental rather than physical. It is usually found, then, in cases associated with hypochondriasis, and such cases are rebellious to medical measures.

So you can see that pruritus, like headache, is often a very important symptom and is the result of many diseases.

DISCUSSION.

G. S. Hanes: I have enjoyed Dr. Ravitch's paper very much. I hardly think that I am the proper one to open the discussion, as I am interested in such a small part of the anatomy he has included. However, I do not believe that itching in any part of the body is as annoying as it is in the rectum.

We have all heard of, and have all had more or less experience with, what is known as pruritus ani. The few remarks I am going to make will not apply at all to the itching that comes from eating strawberries, or hot tamales, or to that due to excoriation caused by secretions, etc., about the rectum. The pruritus that I want to call your attention to is the pruritus that is purely a local condition, and which heretofore has been thoroughly misunderstood. I was thinking, when Dr. Ravitch spoke of the removal of gall-bladder calculi relieving the itching in one case he mentioned and when he said that an atrophied uterus might cause itching about the vulva, that we never have itching in any part of the body for which there is not some definite cause somewhere. Of course, we see cases in which there is general itching, distributed over the body, but where we have definite, localized itching, it is due to disease either at the point of itching or it is reflected to this point. The reason why we have not been successful in cases of pruritus ani of the type that makes a man go frantic, is because our operations and treatment have been directed to the skin or outside, while the disease is on the inside. There is a quack, whose name I will not mention, but who ought to have credit for saying that these cases begin as an infection of the mucous membrane in the lower part of the rectum. The patient does not feel it and does not know it, because there are scarcely any nerves in the mucous membrane of the rectum, but when the condition extends into the anal canal it comes in contact with the most sensitive nerve elements in the body, and they experience a sensation of itching, and until the condition in the mucous membrane of the rectum is relieved we can make all the applications on the outside that we want to and the patient will not get well. Dr. Ball and other surgeons have advised certain operations to be done upon the skin, cutting all the nerves around the anus, etc. When I was in London, I saw a number of patients operated upon by Dr. Mummery after Ball's method, and not a single one of them was entirely well. To cure this disease we have got to go to the inside. It begins there and a well-established case will never be cured until we go on the inside and remove the exciting cause. Then, and not until then, will the patient be cured.

W. F. Boggess: To the general practitioner this is an exceedingly important and practical subject. I know of no more distressing cases

with which we have to deal than patients suffering with pruritis. There is no sensation so hard to control as that of itching.

I was glad to hear Dr. Hanes say what he did about pruritus ani. I have seen the nerves cut and great areas of skin taken off without any relief, and I advised a patient not long ago not to allow the skin of his rectum and buttocks to be taken off because I did not believe it would do him any good; that the trouble was probably higher up. I have advised such cases to consult a proctologist and have the rectum looked into, feeling sure that more serious trouble would be found, and that not until it was removed would they get relief.

Dr. Ravitch spoke of "winter" pruritus, as it is called, which we so frequently see and which is very distressing, not alone in neurotics and hypochondriacs, but also in my experience, in hyperchlorhydriacs. It is a very distressing symptom and, until the digestion is looked after, the patient will not get any relief.

Dr. Ravitch spoke of anaphylaxis. That is a mighty fine term; it sounds good and all that, but I do not think there is any subject so little understood as that of anaphylaxis. I think it is a term that is frequently used to hide our ignorance, or to assign as a possible cause of some condition a term that nobody knows much about.

While I believe that pruritus ani, pruritus vulvae and pruritus vaginae are practically always dependent upon local conditions, there are some cases of pruritus generally throughout the whole body, which are dependent upon constitutional conditions and not local inflammatory conditions. In these cases of general pruritus, I think the condition is most frequently an auto-intoxication, and that by looking after the digestion and building up the general condition of the patient, the pruritus will be relieved.

I believe, as Dr. Ravitch has stated, that where pruritus about the rectum or vulva has existed for years, the "itching habit" has become established, and removal of the cause does not always stop the itching. I have seen that demonstrated in cases operated upon for rectal disease; the itching persisted after the exciting cause was removed.

Bernard Asman: The pathology of pruritus of the anal region has undoubtedly been imperfectly understood for many years. The question whether pruritus of the anal region is a symptom or a disease has been discussed time and again. I am glad to note that Dr. Ravitch said, if I understood him correctly, that pruritus is a disease of the skin characterized by itching, or words to that effect. I believe that pruritus is essentially a disease. I know that a good many authorities have stated positively that pruritus of the anal region is a symptom and not a disease. I think, upon a little reflection, we can arrive at a proper definition of this term. Pruritus is not itching alone. If we are to use the term, as it

is ordinarily used, to designate a certain condition found about the anus, it means more than simple itching. It is true that itching is the most pronounced symptom, but it is not all of it. If that were the case, then after relieving the condition of which the pruritus was a symptom, the itching would be relieved, but we often find that it persists. The reason for this is this: While pruritus may have its origin as the result of some disease, such as hemorrhoids, blind internal fistula, or ulceration anywhere inside the rectum, producing a discharge which flows out upon the surface of the skin surrounding the anus, resulting in constant irritation of the skin which goes on to inflammation and ulceration, still it often does not clear up when the primary cause of the trouble has been removed. It follows then, that in such cases pruritus is a disease which requires for its cure, not only the removal of the cause, but attention to the diseased skin as well. It is undoubtedly true that the quack referred to by Dr. Hanes, has given us some very good ideas in regard to the causation of pruritus. I believe, though, that they are mostly along the same line as the ideas given us by a good many authors in recent years.

We find that, in many instances, this condition is caused by a submucous fistula, frequently so small as to be easily overlooked, but upon inspection of the anus we will find perhaps a drop, or two or three drops, of pus. If this tract is found early in the course of the disease and eradicated, the pruritus will be relieved, but if it has existed for a considerable length of time, attention to the skin itself is necessary. The skin condition can sometimes be relieved by the application of local agents, if the skin is not too much thickened. Very often relief will follow the application of monochloroacetic acid, dilute, and, after desquamation is complete, the application of compound tincture of benzoin will relieve the condition entirely. If the skin is very much thickened and the terminal nerves very much diseased, it becomes necessary to cut these nerves, or to in some way get rid of them. Instead of peeling off the skin all around the anus, as is advised by some men, the same result can be obtained by cutting narrow strips of skin from around the anus, outward as far as the disease extends, say 1-8 or 1-4 of an inch in width, leaving strips from 1-2 inch to 1 inch wide between the denuded area. After this has been done, the diseased nerves going to the remaining strips of skin should be severed by passing the knife beneath them, after which the severed edges may be brought together by suture, or the denuded areas may be left to heal by granulation, as preferred.

It has been stated by many authorities that pruritus of the anal region is practically incurable. I believe that is a mistake; that these cases are curable. First seek out the cause, whether it be a submucous fistula, or a number of tracts in the submucous area leading down into

the anal canal, or what-not—seek the cause and remove it, and then attend to the diseased condition of the skin.

As to pruritus being a mental condition, that may be true of pruritus of other regions of the body, but I do not believe it is ever true of pruritus ani. In my opinion, distinct pathology exists in each and every case, and in order to cure pruritus ani, this pathology must be sought out and eradicated, and then the diseased condition of the skin must be attended to, either by means of local applications, or surgical procedure if necessary. If this is done, I believe that practically all of these cases can be perfectly and permanently relieved.

W. A. Jenkins: There are just two points that I want to make. The first is that pruritus is essentially and always a symptom; never a disease—begging Dr. Ravitch's pardon. I do not think he meant that we should interpret that statement in a very straight-laced way. It seems to me that the experience of the essayist, as well as the experiences detailed by the specialists who have spoken, all tend to prove that pruritus is a symptom, and I believe that is their belief in spite of Dr. Asman's statement that it is a disease and not a symptom. Even in the cases Dr. Ravitch mentioned, and in all other cases where pruritus persists following operations, where the pathological condition has existed a sufficient length of time to give rise to a secondary disease focus, we must still regard this as a symptom and not as a disease. We might just as well say that the pain following a neuritis, remaining for a number of hours and temporarily clearing up, is a disease. Pruritus is no more to be regarded as a disease than jaundice. Nobody now regards jaundice as a disease, but simply as a manifestation that leads us to search more deeply for the true cause of the trouble. The same thing might be said of albuminuria. It is not a disease; there is always a pathological or physiological condition backing it up, and that is the disease condition; the other is merely a symptom.

The other point I wish to make is with respect to diagnosis. We should always make an appropriate, thorough, painstaking search, intelligently interrogating every organ of the body and every physiological function of the body in so far as we are able to do so with the means at our command. We are perhaps too prone to alight upon the most prominent symptom, or group of symptoms, and be satisfied with that, whereas if we would approach it from another standpoint, and make careful interrogation of the various organs and functions of the body, we would be able to arrive at a proper solution of many of these problems.

E. S. Allen: I agree with the point brought out by Dr. Hanes; that pruritus, from an etiological standpoint, is the result of a toxic condition affecting the nervous system. This toxin may be

of bacterial or chemical origin. We know that certain toxins manifest an affinity for, or a selective action upon, certain types of cells. I think therefore, we can readily conceive that certain toxins may have an affinity for special nerve areas.

I have had the pleasure of examining quite a number of specimens submitted to the laboratory by Dr. Ravitch, and almost invariably the specimens he sends in are loaded either with indican or oxylates, one or both, the oxalic acid condition being especially predominant, and is evidence of the great wear and tear that is going on in certain nerve areas. The presence of indican indicates that putrefaction is going on in the anal canal.

There is no doubt that, in the great majority of cases, pruritus ani is the result of pyogenic infection in the anal canal, the bacteria themselves, by their presence, irritating the nerve terminals, or producing irritation by their toxins, resulting in nutritional interference with the nerve terminals and causing a disturbance of function which is manifested by itching. Very frequently we have a neuro-pruritic condition, with an hyperemia, and after this condition has existed for a considerable length of time, certainly changes must take place around the nerve terminals and even after the infecting focus has been dissected out, the symptom of itching continues to manifest itself because of the repair of the tissue that must take place. When there is no longer any condition there to irritate the nerve trunks or terminals, this new material is thrown out, organization takes place, fibrin and fibroblasts develop and contract, producing such changes around the nerve terminals as to interfere with their function, and instead of the physiological function, we have a pathological function in the way of itching.

I can testify, from personal experience, that toxic pruritus is very frequently accompanied by urticaria. It is absolutely poisonous for me to eat one oyster, or drink a small glass of beer. I have tried it on too many occasions to say that it is a coincidence. In each instance I would develop a most intense general itching, all over the body, usually accompanied by urticaria.

In doing laboratory work for Dr. Ravitch, I have been very much impressed by the great number of these cases presenting indicannuria and oxyluria, and I have come to believe that there must be some association between the presence of indican and oxylates in the urine and the manifestation of some skin lesion.

M. L. Ravitch, (Closing): I have very little to say in closing. Dr. Hanes takes a little bit of the subject and goes a long way with it. I did not say that an operation never does any good. What I did say is that we must find the cause. If it is due to hemorrhoids, they must be removed; if it is due to fissure, the condition ought to be corrected, but in many obscure cases

we are unable to find the cause. I remember several cases that were operated upon by a certain proctologist, and the skin removed about the anus, after which they landed back in my office and in sheer desperation I treated them with X-rays and they got well. Again, other cases in which I used the X-rays did not get well. The proctologists are prone to be a little too enthusiastic about operation for the cure of this condition.

As to anaphylaxis, of course none of us knows just what this process is except that the patient manifests an idiosyncrasy to certain drugs or foods. For instance, I had a patient who first had urticaria, and after this had cleared up she developed an erythema. On one occasion, when she had a very bad cold, she called in a physician who put her on five grains of salol and five grains of quinin. Such a violent urticaria developed that I thought that woman would go insane, and she was very sick for several days. Some months later it became necessary to give her a tonic, and I put her on tincture of cinchona compound, to see whether it would have the same effect on her as the quinin. After she had taken one dose her mother called em up and said that her daughter was in agony; she could not swallow, was delirious, had a horrible headache, and was broken out all over her body.

I have patients who cannot drink milk, because it acts upon them like poison.

I do not agree with Dr. Asman in regard to the use of monochloroacetic acid, applied to the rectum, or to any mucous membrane, because it will do more harm than good. In these cases the skin is either hypertrophied or atrophied and you simply add to the trouble.

Bernard Asman: I said, or intended to say that the acid should be applied very lightly to the skin around the anus, and not in the rectum.

M. L. Ravitch: I wish to repeat that, in the beginning, pruritus is a disease and, moreover, a disease of the skin. I agree with Dr. Allen that many cases of pruritus are of toxic origin. I have had a good deal of experience with these conditions, and I believe that skin lesions are closely associated with uric acid and indicannuria.

SCARLET FEVER.

By WM. SANDERS, Louisville.

Scarlet fever is an acute infectious, contagious disease, characterized by high fever, rapid pulse, a punctiform scarlet rash and a somewhat marked tendency to nephritis.

The etiology of scarlet fever is not definitely known. That it is caused by a microorganism does not admit of doubt but the specific germ has not yet been isolated. Mallory found, in the epidermis and skin after death, spherical, oval and elongated protozoan bodies which he regards as the cause of the

disease. W. J. Class, of Chicago, reports the discovery in the scales of the epidermis and in the throats of scarlatinal patients a diplococcus resembling a large gonococcus which presents characteristic features in both its morphology and its mode of growth, but it has not been proven that either are the cause.

In 42 fatal cases of scarlatina Baginsky and Sommerfeld found a streptococcus in all the organs and also in the blood and bone marrow. From this and other reports it is safe to conclude that it is present in all cases. Whatever may be the primary cause most observers are certain that streptococci are the direct cause of the secondary symptoms. "They are so constantly present and so active in the production of the more serious symptoms and complications that they must be regarded as important factors in the production of the clinical picture which we know as scarlet fever. The disease as it commonly appears is a mixed infection, the more malignant and fatal symptoms being due not so much to the primary as the secondary infection. Staphylococci and diphtheria bacilli are sometimes found in conjunction with streptococci."

Successful inoculation of the disease has been performed with the blood serum, nasal and pharyngeal secretions showing that the specific germ of scarlet fever must exist therein.

It is doubtful if the disease can be spread by the patient's breath, but it may be from the scales during desquamation and at any time from all the excretory of the body. The germ is of extreme vitality and may exist for years in unused clothing. Infection can take place from carpets and furniture of the sick room and in fact anything that has come in contact or close proximity to the patient.

Age is a predisposing factor in the cause of scarlet fever. Half the cases are said to occur before the 5th year and 90 per cent before the 10th. Nursing infants generally escape, but adults are occasionally affected. One attack generally confers immunity but second attacks are not extremely rare.

The characteristic lesions of scarlet fever are those of the skin and mucous membranes of the mouth and throat but these generally disappear after death. Those found in the different organs are the result of high temperature or pyogenic infection. The liver and spleen are engorged; the muscles reveal granular degeneration; and the kidneys show lesions of hemorrhagic nephritis.

There are three varieties of scarlet fever: simple, anginoid, and malignant.

In the simple, or ordinary type, the invasion is usually sudden, and is characterized by vomiting, fever, sore throat, and rapid pulse. In older children a chill is sometimes the first symptom; in younger, a convulsion.

The vomiting is not accompanied by nausea and is usually repeated several times. The temperature is frequently found to be 103 degrees F. at the first visit and may go higher on the first day. An initial temperature of 104-105 degrees F. indicates a severe attack; below 102 degrees a mild one. The fever reaches its highest point at the height of the eruption, then begins to subside and becomes normal at a period ranging from the 9th to the 15th day. It is sometimes remittent and in mild cases almost intermittent in character. The pulse is very rapid, out of proportion to the fever. The respiration is hurried; the appetite lost; the bowels constipated and the urine is scanty, highly colored and often albuminous.

Sore throat is one of the earliest symptoms. The pillars, tonsils and walls of the pharynx are bright red in color and numerous dark red macules may be seen on the hard palate. In severe cases the tonsils may be studded with follicular spots or may be covered with a false membrane. At first the tongue is covered with a heavy white coat with red papillae projecting through. In a few days this coat disappears leaving the surface clean and red and the papillae enlarged. This is the strawberry tongue pathognomonic of this disease. Sometimes this is the only symptom by which a diagnosis can be made.

I saw a typical case of chicken pox complicating a mild case of scarlet fever. The first examination failed to reveal the latter disease, but in a few days the exfoliation of the white coating on the tongue led to the discovery of a faint scarlatinal rash in the groin.

The eruption usually appears during the first twenty-four hours. It is a scarlet red punctiform rash. It begins on the neck and chest and spreads rapidly over the entire body. It lasts from five to seven days and is followed by a flaky desquamation. The period of desquamation may last from ten to thirty days.

Restlessness, headache, insomnia, delirium and convulsions may occur during the course of the disease.

In the anginoid type of scarlet fever, the throat symptoms predominate. The tonsils are intensely swollen and are covered with a false membrane. The fever is high and the prostration profound. Ulceration of the throat frequently occurs. Death may result from exhaustion, asphyxiation, pneumonia or hemorrhage.

In malignant scarlet fever the onset is abrupt, with a chill, vomiting or convulsion. The fever is very high (106 degrees F.-107 degrees F.) the pulse is rapid and feeble; delirium sets in, and is followed by coma. Death may take place before the appearance of the rash.

Nephritis is a complication that must always be looked for. It generally develops during the third or fourth week after the fever has subsided and convalescence is well under way. It may follow a severe or mild case. In severe attacks of nephritis there may be suppression of urine, general edema and uremic symptoms. Recovery is the rule in many cases but uremia may be the immediate cause of death in others.

The infection may attack any part of the body. The middle ear, heart, lungs, glands of the neck and joints may be the seat of inflammation or suppuration.

The diagnosis of a typical case of scarlet fever should not be difficult when we keep in mind the characteristic symptoms. The abrupt onset, vomiting, high fever with very rapid pulse, the erythematous condition of the throat, the macules on the hard palate, the enlarged papillae on the tip and edges of the tongue, and the early appearance of the rash. The atypical cases may be confounded with acute tonsillitis, diphtheria, measles, rubella and the various drug and food eruptions, but a clear history of the case with a close observation of the throat and tongue during a few days ought to clear up the diagnosis in most cases. Sometimes desquamation decides a doubtful case. In severe throat cases we can always have a culture made to differentiate from diphtheria.

When we consider that the mortality of scarlet fever varies from three to forty per cent. in different epidemics, it emphasizes the importance of a strict quarantine to prevent the spread of the disease. The patient should be isolated for at least four weeks or until desquamation is complete, then only after a thorough disinfection of himself and everything connected with the case, should he be allowed to mingle with other children. The physician who attends a case cannot exercise too much care for the protection of his other patients. I make a practice to cover my hair with a towel and wear a gown over my clothing when in the sick room, and between visits the gown and towel are sprinkled with formaldehyde and wrapped in newspaper, so they are always freshly disinfected. The hands and face should always be washed in some antiseptic solution after each visit.

As we have no specific for scarlet fever our aim should be to treat the symptoms as they arise and prevent, if possible, the complications. The patient should be kept in bed on a liquid diet during the febrile period. The bowels should be opened with small, repeated doses of calomel and kept open by mild laxatives or hy enemata. The urine should be examined frequently. I find a combination of potassium acetate, spirits aetheris nitrosi and liquor ammonii acetates in appropriate

dosage in camphor water acts not only as a mild febrifuge but as a diuretic as well. Fever above 103 degrees F. calls for bathing. The nose and throat should be kept clean with mild antiseptics such as Dobell's solution diluted. In severe cases stimulants may be required. Strychnine and digitalis should be given. I do not favor alcohol on account of the possible effect on the kidneys. Otitis requires the treatment demanded by the disease in other conditions. Restlessness and nervous symptoms are sometimes relieved by cold to the head or by small doses of bromides. Nephritis should be treated by cathartics, hot pack, diuretics and stimulants.

Antistreptococcic serum has been used in the treatment of scarlet fever and some very favorable results have been reported. I used it in a case of puerperal scarlet fever without result. I also used streptococcic vaccine on this case with no result. This, of course, was not a fair test.

In conclusion I want to report one case of the severe anginose type treated with antitoxin:

Burt S., age 10 years, during the night of February 15, 1910, was seized with an attack of vomiting, next day rash appeared, complained of sore throat. I saw him on the morning of February 17, 1910, rash covered the entire body, conjunctiva injected, tongue coated with red papillae on tip and edges, tonsils swollen and covered with small areas of exudate which were easily removable. Temperature 103 degrees F., pulse 120; patient restless. There was a noticeable swelling at the angles of the jaw. February 18, patient very restless, pain on swallowing, swelling at angle of jaw increased, tough membrane covered tonsils, bleeding on removal, rash more pronounced; temperature 104 1-2 degrees F., pulse 136, vomiting all medicine and food. At 6 p. m., temperature 105 degrees F., pulse 140. I then gave 3000 units of antitoxin. February 19, 8 a. m., temperature 102 degrees, pulse 100; 6 p. m., temperature 101 degrees F., pulse 90. February 20, 8 a. m., temperature 101 degrees, pulse 90; 5 p. m., forty-seven hours after the administration of antitoxin, temperature normal and the rash had faded away. The convalescence was uneventful with no complications. The desquamation in this case was extreme, even to the nails of the fingers and toes.

DISCUSSION.

David C. Morton: It seems to me that scarlet fever should be termed "treacherous fever", because the sequelae of this condition are more frequently apparent after mild cases than they are following severe cases. Notable among these sequelae is scarlatinal nephritis, which so often

follows in the wake of the disease. To employ a paradoxical phrase, it might be said that in such cases the disease is one in which the patient is much sicker after he gets well than he was while he was sick. I had an opportunity of seeing a case of this kind in a young man, about 27 years of age, who, from the description he gave me and from the fact that he had a bran-like desquamation of the skin on the chest, particularly above the right breast, appeared to have had an unobserved attack of scarlet fever five days before I saw him. When I saw him he had an active, acute nephritis, and it was only upon carefully questioning him that I elicited the history of a very transient, erythematous eruption, which had occurred about five days previously. Curiously enough, this young man gave a history of one of those persistent albuminurias, for which he had been under the care of no less eminent a man than Dr. J. H. Musser, of Philadelphia. I had hoped, on a recent visit to Philadelphia, to discuss the case with Dr. Musser, but, unfortunately, he died while I was on the way there. It is a curious fact that nephritis following scarlet fever often occurs in patients whose kidneys have shown some previous evidence of abnormality, such as an illy defined form of albuminuria.

I would like to mention one point in the differential diagnosis of scarlet fever from other more or less erythematous eruptions. Upon pinching the skin over the sternum between two fingers, there will be extravasation of blood, which, if the condition is scarlet fever, will persist for a considerable time, but will not persist if the condition is other than scarlet fever. I saw this tried at St. Augustus Hospital in Vienna, last year, during quite an epidemic of scarlet fever, and in practically every case which afterwards proved to be scarlet fever, upon pinching the skin the extravasation would appear and persist, while in those cases in which scarlet fever was not present, it did not persist.

I was very much interested in the doctor's description of the case which he treated with diphtheria anti-toxin. Of course, it is not impossible that this case could have been a combination of scarlet fever and diphtheria. I would like to ask Dr. Sanders if a search was made for the Klebs-Loeffer bacillus before or after giving the anti-toxin, or at any time during the course of the illness.

M. L. Ravitch: I have seen quite a number of cases of scarlet fever in consultation. There is one thing that I think should be borne in mind in connection with the diagnosis, and that is the manifestation of so-called "goose-flesh" in all these cases. Another important diagnostic point is dermatography; I have never seen it fail in a case of scarlet fever. If you pinch the skin it will first turn pale, then red, then white and remain that way for from two to five minutes.

I have seen cases which were not scarlet fever have a scarlatinal form of eruption, sometimes in-

duced by toxemia, by food or by drugs. Some cases of measles and German measles are complicated by scarlet fever.

In many of these cases the administration of diphtheria antitoxin will do a great deal of good. Dr. O'Connor will remember a Sister at the Sacred Heart Academy who had purpura hemorrhagica, with all the throat symptoms of scarlet fever. She had purpura all over the body and even the intestines were affected. I gave her five thousand units of antitoxin and she got well.

Occasionally scarlet fever is accompanied by herpes, sometimes on the lip and sometimes over the eyes. I have seen cases accompanied by urticaria; others where eczema developed and sometimes it is complicated by tuberculosis.

In regard to Dr. Morton's case, while I have not seen this patient, it is very doubtful whether this was a case of scarlet fever, as he says the patient was 27 years of age. I knew this young man's brother, having treated him for eczema for several years. He then consulted a homeopath and died about a week later. In the case mentioned, therefore, it seems that albuminuria and glycosuria was a family characteristic, and I am inclined to believe that this was not a genuine case of scarlet fever but probably some other form of erythema.

E. F. Katemann: I wish to speak to just one point, and that is the possibility of a person having two attacks of scarlet fever. I have seen quite a number of such cases, but invariably the second attack was a mild one.

I believe we often lose sight of the fact that scarlet fever may occur without an eruption. This point was especially impressed upon me during the last epidemic we had here. I have seen a number of cases with coryza, low temperature, fast pulse, glandular involvement, etc., but without any eruption. In such cases, not being positive as to the diagnosis, it has been my practice to quarantine the patient, but the family, as a rule, seeing that the case was a mild one, would not strictly obey orders, with the result that in two or three days or a week, some other member of the family would contract the disease, thus confirming the diagnosis.

I believe that many cases of albuminuria can be traced directly to an attack of scarlet fever, most frequently of a mild type.

Bernard J. O'Connor: Most of the points in connection with the diagnosis of scarlet fever have been well taken. Many cases of scarlet fever present a great many difficulties in the way of a diagnosis. Possibly some of the points mentioned have not been sufficiently accentuated. One of these is the pulse. Many of the speakers have mentioned a rapid pulse, but not a word has been said about a full, bounding pulse. In diphtheria the pulse is rapid, but is of considerably lower tension than in scarlet fever. Another point is emesis—not one or twice, but keeping up for twelve to twenty-four hours, or until

the bowels move well, emesis without any apparent cause. The temperature in scarlet fever is anomalous, as compared with the temperature in the ordinary run of infectious diseases. As a rule, a high temperature is a rather favorable prognostic symptom, but in scarlet fever apparently the higher the fever the more dangerous the disease. This does not always hold true, however.

Glandular hyperplasia is another manifestation that has not been mentioned. In scarlet fever glandular hyperplasia is not confined to the cervical glands, but all of the lymph nodes in the body will be found to be slightly enlarged, and slightly tender in well-marked cases.

Just a few words about treatment. My experience has been that nephritis does not always follow scarlet fever. Scarlatinal nephritis is a common condition, but it most frequently occurs in neglected cases—some of them never having been under the care of a physician. During the past winter, I am sure that there were a large number of cases of scarlet fever of a mild type that never reached our hands. Scarlatinal nephritis can be prevented in almost every case by the early use of hexamethylenamin. If given in sufficiently large doses right from the beginning, it is seldom that any grave disturbance of the kidneys will follow the attack. This has been borne out by the testimony of men throughout the whole country.

The question of treatment of scarlet fever complicated by diphtheria is a very important one. Diphtheria frequently occurs as a complication of scarlet fever, and it does not always occur with a membrane. Therefore, I think it is advisable, in every case of scarlet fever, to make a culture. I saw one case last year, which later fell into the hands of Dr. Katzman, in which I made a diagnosis of diphtheria, but later a typical scarlatinal rash developed and the patient died within thirty-six hours after the onset of the symptoms. I saw this case for another physician, but did not have a culture tube with me at the time. In reporting to the doctor I advised him to make a culture and have a bacteriological examination made.

Just a few days ago I saw a case which accentuated the fact that we may have diphtheria without a membrane formation. This patient had symptoms so suggestive of diphtheria that I began the administration of antitoxin before making examination of the slide. There was no evidence of a membrane formation. Bacteriological examination, however, confirmed the diagnosis. In two days, under the administration of antitoxin, the symptoms had disappeared.

O. H. Kelsall: Some interesting points in connection with scarlet fever have occurred to me. One is the difficulty of diagnosis in the colored race. How are we going to diagnose scarlet fever in a negro with a dark skin? I remember slipping up in a case of this kind some years ago. The patient was a colored boy, about 17 years old,

who presented symptoms of a rather severe pharyngitis and fever, and I did not suspect scarlet fever. After a few days' treatment he felt better and went back to work. Three or four weeks later I happened to see him again and noticed that he was "peeling." In the colored race our diagnosis must be based on such symptoms as a strawberry tongue, the appearance of the throat, etc.

In regard to scarlatinal nephritis, as has been stated here to-night, this is more apt to develop late in the disease. I think one of the best prophylactic measures is to keep these patients warm. When the skin is in the exfoliating condition, chilling of the surface of the body is very apt to result in congestion of the kidneys, thereby predisposing to nephritis. Therefore, I believe that, during the exfoliating period and for some time afterwards, especially in chilly weather, these patients should be kept in a warm room.

Some years ago I read something about the sulphide of calcium as a prophylactic against scarlet fever. I have made use of this agent in all cases where there were other children in the family exposed to the disease, and it has been my uniform experience to never have more than one case of scarlet fever in a family. Several years ago I had a case of scarlet fever in a boy, about seven years of age, whose brother, nine years old, slept with him. I put the brother upon sulphide of calcium and, while he had been exposed to the infection as thoroughly as any one could be, he did not develop the disease. A few years ago I had a case of scarlet fever in a family in which there were eight children. I practiced isolation but, as you all know, this is never perfect. However, I put them all on sulphide of calcium and there was only one case in that family.

In my own family, about two years ago, my little boy, seven years old, had a case of scarlet fever of the anginoid type. I made an attempt at quarantine, but even with a trained nurse I must admit that it was not perfect. Some of the little ones would run in occasionally. I put them all on sulphide of calcium and no further cases developed. This has been my uniform experience, and I make it a rule to give all exposed children sulphide of calcium.

Wm. A. Keller: This subject is one of great importance to the general practitioner and specialist alike. A great many points have been brought out, some of them good and some of them not so good. I have always noticed that the vomiting in scarlet fever is of a projectile type, and I have also noticed that it is frequently the first symptom that manifests itself.

In regard to the pulse and temperature, while I would much rather have a temperature of 101 or 102, with a not too rapid pulse, still those with a higher temperature are much better to handle. I think the prognosis depends, to a great extent, upon the severity of the epidemic. In some epi-

denies the disease is very severe, while in others it is comparatively mild. One of the speakers mentioned the fact that the majority of cases of scarlet fever do not come into the doctor's hands, and I quite agree with him. On quite a number of occasions people have brought their children to me and asked if they had had scarlet fever, and they were peeling at the time.

I do not believe that diphtheria is a complication of scarlet fever nearly so often as it is claimed to be, and that the membrane we find is simply a scarlet fever sore throat.

One of the speakers reported a case of scarlet fever in a young man, 27 years old. I remember seeing a case in a woman, 60 years old. She had nursed her grandchild through a very severe attack, and after the child got well she developed a typical case of scarlet fever, but pulled through in good fashion.

I agree with Dr. Nickell in regard to relieving the work of the kidney by hot baths, and proper diet. I always give instructions that the child shall be put on an absolute milk diet, and I have seen very few kidney complications.

I also agree with one of the other speakers in regard to keeping the patient warm. In most instances, nephritic complications come on about two weeks after the patient has begun to convalesce. I believe this is due to exposure to cold; the body gets chilled, and of course this predisposes to an infection of the kidney.

As to middle ear complications, I have had quite a little experience in treating ear cases, and I do not know of anything that is so hard to manage, or where less can be promised in the way of good results, especially in long-standing cases. As Dr. Nickell stated, I think it is a good plan to open the ear and thoroughly drain out the pus. If this is done I do not believe the results will be so bad so far as permanent loss of hearing is concerned. However, we must bear in mind that the average doctor when he has a case of scarlet fever is thinking more about that condition than he is of the ear. He has a serious disease to contend with, and he is not apt to pay as much attention to the ear as he does to the high temperature, kidneys, etc. It is certainly a disease that will make any one "sit up and take notice."

A. W. Mitchell: The subject of scarlet fever is one of the most interesting of any of the exanthemata. It is also one of the most dangerous diseases to which children are subject, because of its complications. I will not take up all of the various complications, but will confine my remarks principally to the most serious of these, which I consider to be nephritis, otitis media, and cervical adenitis. The latter is a frequent complication and, when suppuration occurs, the most troublesome one. With the first sign of a swollen gland, apply an ice-pack and keep it constantly in position, if possible, day and night. It is true, this is attended with difficulty in some cases,

at which times cold compresses, with water at a temperature of 50 or 60 degrees, covered with oiled silk and changed every 30 to 60 minutes, gives excellent results. As regards middle ear suppuration, this is a complication in from 10 to 30 per cent. of all cases of scarlet fever. When we consider how many cases of permanent deafness have and do occur, every year, as a result of carelessness, or a lack of even ordinary knowledge of the diagnosis of these ear affections, we do not feel disposed to congratulate the member of the medical profession on their ability to complete their cases. Noy has collected statistics of over five thousand deaf mutes, almost 600 of whom owe their condition to otitis following scarlet fever. I think any one with ordinary discretion, who knows anything about the elementary principles of nasal diagnosis, can tell pretty well when pus is present, and in view of the grave possibility of mastoid involvement, sinus thrombosis, and jugular bulb infections, it is imperative that pus in the middle ear be promptly detected and evacuated, and if we will perform paracentesis early, evacuate the pus thereby giving proper drainage, and institute the necessary after-treatment, we can prevent a large per cent. of deafness to which these unfortunates are so very liable.

As regards nephritis following this affection, I do not quite agree with the essayist in regard to the use of digitalis in a condition where the kidneys are already more or less crippled. Cases are on record in which, after three or four days, the patient developed an acute general nephritis. In these cases of scarlatinal nephritis, active measures to increase diaphoresis and thus relieve the kidneys, to my mind, should be instituted. In these cases it is by attempts to force the kidneys to act by the use of digitalis and alkaline diuretics that we do an immense amount of harm. Digitalis drives more blood into the kidneys which are always deranged, and increases their congestion. Alkaline diuretics disturb the stomach, which shows food intolerance. Therefore, in this class of cases, the best treatment is a carbohydrate diet, because it gives no by-products for the already irritated kidney to work on, and by wet packs and hot baths, supplemented by colon flushing with warm saline solution, increasing diaphoresis and thereby relieving the kidneys, the results are much better than by the internal medication just referred to.

I am not very sanguine about serum therapy in the treatment of scarlet fever, because, in a condition where we do not know the causative agent, I do not understand how we can administer rational therapy. Scarlet fever is supposed to be due to a mixed infection, and the administration of anti-streptococcal serum may possibly, in certain selected cases, give good results. I have made a number of experiments along this line, but they have never been attended with the degree of success that I would like to see.

T. K. VanZandt: There has been so much said on this subject that I wish to mention only one point; that is, the effect of the diphtheritic antitoxin in scarlet fever. I recently had a case of diphtheria complicating scarlet fever. The symptoms of scarlet fever were typical for the first ten days. Then a membrane developed in the throat which I at first thought was scarlatinal. I had Dr. Allen make an examination which was negative, and a second examination also proved negative. Then he made a culture from the membrane and it was positive. I gave the child 19,000 units of antitoxin. The diphtheria was of the laryngeal type, and the tonsils were very much enlarged. The child is now in the second week of the diphtheria. There is still a great deal of difficulty in breathing. The temperature has been running around 102; pulse 140 to 150. To-day the pulse is 120 and the temperature 101.

Wm. Sanders, (Closing): I wish to thank the gentlemen for their discussion. Answering Dr. Morton's question, I will say that I had no search made for the diphtheria bacillus, although I have thought since that I should have done so. I was surprised that the case cleared up so quickly.

CLINICAL CASES.

REPORT OF CASES.

By D. Y. KERN, Louisville.

CASE I.—RECURRENT CARCINOMA (MULTIPLE).

Mrs. S. C., female, white, widowed, age 72.

FAMILY HISTORY.

No history of cancer in family. Has three children living, youngest age forty, all in good health.

PERSONAL HISTORY.

Has always been a very active woman with fairly good health. She was operated upon thirty years ago for some rectal condition with an ideal result. Three years ago the axillary glands with right breast were removed, which proved to be carcinoma upon microscopical examination.

The line of incision was exposed to the X-ray several times after the operation. During the past few years she has had an occasional attack of gastric distress, usually being relieved by elimination and digestants.

I was called to see the patient on August 29, 1911, in an emergency, and found the following condition:

Patient was in a state of collapse with profuse perspiration, pulse 140 very irregular, marked dyspnoea unable to breathe except in the semi-supine position. Physical examination revealed a markedly distended stomach displacing the heart upward and to the left

causing it much embarrassment. Chest examination negative except few large rales in the bronchi.

Patient suffered no pain but looked distressed. Spent a very uncomfortable night but improved under rest and elimination. Dyspnoea was marked on slight exertion, during entire course of illness.

Urinalysis showed a trace of albumin with very small amount of urine. No casts were present.

Patient improved for a few weeks and then began to decline which was gradual until the end. Slight induration was present along the line of incision with two or three small hard nodules at the upper end of incision.

Slight tenderness on pressure was present all the time over the upper abdomen with very tender spot at the splenic flexure of the colon.

Constipation only slight. Pain in the early part of illness in right shoulder and scapula; later the most marked and constant pain was over the pyloric end of the stomach and liver region radiating to the right axilla.

Chest examination negative until six weeks before death when dullness appeared over lower part of the right lung with absence of breath sounds.

The dullness gradually increased until the lower two-thirds of the right lung was silent. Throughout entire illness nausea was marked at intervals with only slight vomiting. No blood ever present in vomitus or in the stools. During the last three weeks of illness she was unable to take more than one or two ounces into the stomach without becoming nauseated. Rectal feeding was used to support her for three weeks or more.

No tumors of the viscera were ever palpable. At no time was the temperature above 99.4 degrees Fahrenheit, pulse ranging from 86 to 106.

Treatment was symptomatic.

AUTOPSY REPORT.

On opening the abdomen the large bowel was all that could be seen, it being distended. The transverse colon was prolapsed into the pelvis.

A portion of the sigmoid was adherent to the uterus and left broad ligament. In the wall of the entire large bowel could be seen many small brownish specks though they were only slightly palpable.

In the mesentery of the large bowel numerous small hard neoplasms were present from the size of a grain of wheat to that of an almond.

These small tumors were in chains, the largest number being in the meso-sigmoid. The appendix was dilated. A tumor the size of a vest button was present on the tip and two smaller ones in the meso-appendix. Be-

hind the peritoneum in the walls of the abdomen were many of these small tumors. Behind the stomach was a mass of these neoplasms possibly one hundred in number which bound the pyloric end of the stomach to the spinal column, causing a partial obstruction. The stomach was small and very flabby. Many small tumors were present on superior surface of the bladder just under the peritoneum. Six or eight were present on upper surface of the right lobe of the liver, all of which were umbilicated. Bile passages distended though otherwise normal.

Right lung was adherent to chest wall. The chest wall being filled with numerous small tumors, also involving the parietal pleura.

COPY OF LABORATORY REPORT.

Louisville, Ky., March 11, 1912.—Section shows liver with isolated areas of fatty infiltration and some network of connecting tissue. One portion of section shows a nodular mass of tissue in which there are groups of spheroidal cells with vesicular nuclei in a mass of rather old fibrous tissue.

MICROSCOPICAL DIAGNOSIS.

Metastasis to liver of an epithelial growth with connective tissue formation with history of a carcinomatous breast and subsequent amputation and the picture in mind of a sclerosed carcinoma with great connective tissue growth. I should associate this metastatic growth with the original growth in breast.

Leon K. Baldauf, A. B. M. D.

CASE II.—CHOREA COMPLICATING PREGNANCY.

Mrs. D. R., female, white, age 27, married. Nationality French-American.

FAMILY HISTORY.

Negative. No history of chorea or any nervous disease in paternal or maternal ancestors except maternal grandmother suffered an attack of hemiplegia in this month, January, 1912.

PERSONAL HISTORY.

Has had diseases of childhood; no other serious diseases. Had abscess at root of tooth two year ago following some dental work.

First menstruation appeared at the age of twelve, second menstruation two years later since which time menstruation has been regular until four months ago when patient became pregnant.

Patient has had none of the unpleasant symptoms of pregnancy. Feels as well or better than she ever felt before in her life.

PRESENT HISTORY.

Patient came under my observation January 2, 1912, giving the following history: Five weeks ago noticed a slight inco-ordination of the muscles of right forearm and hand more marked in the index finger and the

thumb. Next noticed involuntary twitching of the hand with purposeless movements of the forearm, and was unable to write legibly.

In a short time she became unable to handle small objects on account of the involuntary extension of fingers when holding objects.

When patient consulted me she was unable to write, dress herself or even to use the right hand in eating her meals.

PHYSICAL EXAMINATION.

Patient rather small in stature, plump and well nourished. Eye reflexes normal, visible mucous membranes very pale and anemic. Pulse normal; temperature normal; heart and chest examination negative.

Purposeless movements of hand and forearm very noticeable. Movements of hand and fingers consisted of involuntary flexion and extension of fingers at irregular intervals.

No twitching of the face muscles present. Slight inco-ordination of the muscles of right lower limb visible when walking.

DIAGNOSIS.

Chorea, complicating pregnancy in primipara.

TREATMENT.

Patient was instructed to take as much rest as possible, given a carefully regulated diet under good hygienic surroundings. Was given Fowler's solution beginning with minims three after each meal, increasing one minim each day until minims seven were reached. This dosage was continued for ten days then a rest of two days, beginning again with seven minims and reduced until minims three were given which dose she continued till the end of the fourth week. Patient was then given iron and strychnine arsenate in small doses.

Patient having a friend who was a professional masseur was given a massage of the right arm, forearm and hand twice daily. Patient leaving the city on February 7, 1912, free from any involuntary twitches.

On February 26th, I received a letter from the patient stating that she was feeling well and free from all symptoms.

Just a word in regard to the rarity and the mortality of chorea complicating pregnancy: Sebree has collected 154 cases with a mortality of 22 per cent. Buist collected 255 cases with a mortality of 17 per cent. French and Hicks reported only 29 cases which had been observed in Gray's Hospital in the previous thirty years with a mortality of 10 per cent. By various authors the mortality is placed at from 10 to 36 per cent.

Pregnancy in choreic individuals is unimportant while in chorea that does not appear until after conception the prognosis is grave.

The movements may become so intense as to interfere with eating, or sleeping and abortion may occur spontaneously. The appearance of fever is of serious import and at autopsy evidences of malignant endocarditis are found. Williams says the only case of the grave variety he has seen died in spite of the fact that the patient fell into premature labor spontaneously a short time after admission to the hospital.

Sixty per cent. of all cases occur in primigravidae usually occurring in the first third of pregnancy, showing a tendency to persist.

Twenty-five per cent. of all cases occur in the third month of pregnancy. In the case just reported the first symptoms were observed in the tenth week of pregnancy.

Chorea in pregnancy is very rare after the second pregnancy except as a recurrence. The only recorded case occurring for the first time in the fourth pregnancy was of doubtful diagnosis as the movements were confined to the lower limbs.

Prognosis in these cases should always be guarded on account of the tendency to persist for when the disease assumes the gravid type it is attended with great danger.

If the patient appears to be in serious danger premature delivery should be brought on as experience has shown that the emptying of the uterus is usually followed by marked improvement.

Causes of death are muscular exhaustion, heart failure, insanity, or the sequelae of an interrupted pregnancy.

DISCUSSION.

G. S. Hanes: I had the good fortune to be present at the autopsy in the second case reported. There were three features of this autopsy that were very interesting to me. The first one does not pertain at all to the pathology of the case. There was complete ptosis of the transverse colon. Usually where there is extensive or complete ptosis of the transverse colon, there is also ptosis of the hepatic flexure, and also, to a large extent, of the splenic flexure, but in this case these two points seemed to be in normal position. The center of the transverse colon was prolapsed into the brim of the true pelvis. The picture was that of a perfect U, the first arm extending up to the hepatic flexure and the second extending up to the splenic flexure.

The second interesting feature pertains directly to the pathology. I was very much impressed, not having seen a great many autopsies, by the extensive metastatic infection that had occurred in this case. This tumor, as Dr. Keith said, was primarily in the right breast, and was removed two years before the patient's death. There was no evidence of any tumefaction in the original site, except I believe Dr. Keith said there were one or two small masses. The deposits he spoke

of were extensively deposited under the peritoneal lining of the posterior and lateral abdominal walls. A large chain of lymphatic glands extended along the left sacro-iliac synchondrosis, and small deposits were numerous in the walls of the large and small intestines; in fact, they were scattered in and under all the peritoneal structures of the abdominal cavity.

The third interesting feature is that this infection traveled through the chest wall to the lining of the thorax. The serous coat of the thoracic wall, and the serous covering of the lung was involved. The entire right lung was adherent to the thoracic wall. Upon tearing it loose and palpating any part of the surface of the lung, these deposits could be detected.

The most interesting feature of the whole thing is that Dr. Keith got an autopsy. It took a shrewd man to attempt it in this case, and he is to be complimented. Our profession would know a great deal more if we had been doing for many years what he did in this case. It is a very easy matter to make a statement as to what caused the death of a patient when one is absolutely certain that nothing will come of it later, but when an autopsy is held, and you can go in and see exactly what has occurred, then you have gained profound knowledge. Dr. Keith has set an example of the only way in which we can definitely ascertain what causes death in various intra-abdominal, intra-thoracic, or intra-cranial troubles.

Irvin Abell: I wish to congratulate Dr. Keith upon the thorough and detailed account he has given us of this case. What Dr. Hanes said in regard to the autopsy would apply with equal force to the study of the case before death, the thoroughness with which Dr. Keith has gone into the family and personal histories showing familiarity with the patient from all angles.

This autopsy bears out two very interesting facts; first, that all breast lymphatics do not lead into the axilla, that they do pass through the ribs into the intrathoracic structures, and, furthermore, that they pass on through the deep epigastric structures into the abdomen, so that, in doing a breast amputation, cleaning out the axilla does not necessarily mean that all the lymphatics that may be involved are removed.

Another important point illustrated by this case is the futility of doing late operations in the presence of malignant growths. I grant you that it is hard to resist when the patient and the family insist your giving them one last chance, but I do not know but what it is best to refuse operation in such cases, and send them back home with the information that they have applied too late. This would help to impress upon the laity that operations for cancer, to be successful, must be done in the incipency of the condition. How often do patients come to us with a tumor, and say that if it proves to be a cancer, they do not want it operated upon? I have seen many cases

in which operation seemed to disseminate the infection and death was more rapidly brought about. It is absolutely futile to attempt to relieve these patients. We may prolong life slightly, but the greatest good to the greatest number in such instances would come from refusing to operate with the information that we cannot save their lives because the disease has progressed too far. A careful study during life and detailed autopsies, such as has been given us in Dr. Keith's report, will not only increase our knowledge of the condition, but, if spread before the laity, will be of inestimable value in bringing these patients to us at a time when we can really be of service to them.

W. C. Dugan: I wish to congratulate the society upon having heard Dr. Keith's report. I have enjoyed it very much indeed and hope it will be a lesson to all of us to be more thorough and careful in making reports to this society.

Edward Speidel: I would like to ask whether any of the members, besides Dr. Keith, have ever seen a case of chorea complicating pregnancy.

J. Hunter Peak: I have never seen but one case, and that was in a young lady upon whom I had operated some years before for an old empyema. This young lady lived in a neighboring town and was referred to me by her physician there. Later she had an involvement of the clavicle—some bone condition—and a portion of that was removed. When I first saw this woman she was very thin and anemic, presenting the appearance of one in the last stages of consumption. She began to gain rapidly in flesh and inside of a year had gone from 105 to 170 pounds in weight, and was as fine specimen of womanhood as one would want to see. Five or six months after having this trouble with her clavicle, while in seemingly good health, she developed a choreic condition, for which I was called to see her in consultation. The doctor gave her about the same treatment as detailed by Dr. Keith, and she recovered. She later married and became pregnant, and for the first 3 1/2 months had no trouble whatever. Then she developed a choreic condition, and both the patient and her parents were very much alarmed. Her physician asked me to see her, thinking that it might be advisable to bring on a miscarriage. However, her people were very religiously inclined and did not believe in anything of that kind, the girl herself saying that she would rather die than submit to such procedure, and it seemed to me for a time that she would die. I have never seen so many violent, purposeless, muscular contractions of almost every muscle of the body, even of the tongue; she could not talk for days. This condition persisted for about eight weeks, not always so bad, sometimes being controlled by the bromides and other nerve sedatives. The same treatment as before was instituted and she finally recovered. She went on to what was supposed to be full term pregnancy, but I learned later that she was de-

livered of a dead child. She herself made a perfect recovery.

Edward Speidel: I congratulate Dr. Keith upon having seen this case. I have seen nearly every complication of pregnancy and labor, I have never seen a case of this kind.

There are two distinct forms of chorea in pregnancy. The first is that in which a young girl has chorea, and later gets married, becomes pregnant and has what might be termed a recurrence of the chorea. The second and more serious form is that in which chorea presents as a primary manifestation during pregnancy, where there is no history of any previous attacks of chorea. The first form is supposed to be very common and, as a general thing, is a very simple condition that passes away during the later months of pregnancy. I have seen many cases of hysteria and epilepsy aggravated by pregnancy, and it is not astonishing that the same should be true of chorea when we remember that one of the signs of pregnancy is mental and emotional disturbance, probably aggravated by the anemic condition common to this class of patients.

D. Y. Keith, (Closing): I wish to thank the gentlemen for their discussion. I am very glad that Dr. Speidel pointed out the difference between the case I reported and that mentioned by Peak. It is altogether a different disease so far as the pregnancy is concerned. Most authorities tell us that a choreic individual becoming pregnant usually goes to full term without any trouble, but that in an individual with no choreic history, who become pregnant and then develops chorea, the condition is a very grave one. That is the point I wanted to bring out in the report.

I am very sorry that I had to report this case somewhat prematurely. This woman is the wife of a professional singer, who stayed here only a short time for treatment and then went to her home in Michigan. If she lived in the city I would not think of reporting the case until after confinement, so as to see whether the condition would recur, or take on a grave character.

(Later—This woman was delivered of a full term child at her home in Michigan, in the latter part of June, 1912.)

REPORT OF CASES.

By A. DAVID WILLMOTH, Louisville.

CASE I.

LIPOMA OF UNUSUAL SIZE AND LOCATION.

Mr. A., age 37, white, referred by Dr. Willis, of Cromwell, Ky., with the following history:

Patient, farmer by occupation, noticed some twelve years ago that he had a small tumor growing from the left side about one inch and a half below the crest of the ileum. This tumor being painless in character caused him to carry it some seven years before consulting

a surgeon; when operation was advised his friends protested and he decided to defer the matter. At this time the tumor was of sufficient size and was pedunculated so that it required its being carried in a sack. On November 28, when he came to me for operation the tumor measured seventeen and one half inches in circumference and sixteen and one half inches long; the blood supply was very great and was only prevented from being strangulated by the sac being attached to a belt around his waist. The tumor was removed by clamping off the base and removing the mass by incision extending around the entire pedicle; some eight or ten vessels required ligating. This patient was out of bed in five days and was able to return to his home in ten. A small tumor of the same type (lipoma) was removed just above the sight of the large one.

CASE II.

HYDATID CYST OF LIVER.

Mr. C., white, age 27, occupation farmer, referred by Dr. Craddock, Bonnierville, Ky., with the following history, when seen July 21, at his residence with Dr. Craddock and Dr. Hall the following facts were obtained: Patient had had those diseases incident to childhood and had been in perfect health all his life until 57 days previous to my seeing him, when he was taken with what was diagnosed as typhoid fever. Upon being told this he informed the doctor that since typhoid fever was largely nursing in management that he would employ a nurse and send for him when he needed him. The result was that he was paid eight visits by the doctor during the next 45 days. He was not seen for ten days and when called found patient with pulse around 125, respiration ranging from 20 to 30, and temperature from 100 to 103, tongue coated and dry, abdomen distended with a cyanotic appearance of the right side from the anterior superior spinous process of ileum up to and including the skin of the neck.

Percussion revealed a flat note over practically all of the right lung and extending down over the right abdomen to the upper part of the lower right quadrant. A tumor could be easily felt in this area. At the time I saw him his temperature was 102 1-2, pulse 130 and general condition bad, as the right pleural cavity was now about half full of fluid. On examination I made up my mind that I had one of two conditions to deal with in the abdomen plus the condition in the chest. A careful questioning revealed the fact that he had been fond of dogs all his life and had kept one or more about his house, this together with the elastic feel of the tumor caused me to give an opinion that he had either a hydatid cyst of the liver or a car-

cinoма with the chances in favor of the former.

His general condition contraindicating the work in the abdomen I elected to do the simplest work first and relieve him of the mechanical obstruction to his respiration. So with an aspirator I drew away very slowly one gallon of fluid.

In one week the patient had so improved that he demanded that an exploratory incision be made and determine what, if anything could be done with the tumor. So with a thorough understanding with him, his wife, and father. I made an incision to the outer border of the right rectus muscle and went down directly on a piece of the right lobe of the liver which was attached to the abdominal wall. Lengthening my incision downward, I opened the cavity and found this piece, which was entirely separated from everything except the cyst wall, to be all the liver structure he possessed. A large cyst containing about two quarts springing from the right lobe had destroyed the entire liver. This large cyst had six daughter cysts springing from its wall and attached to surrounding structures which contained one and one-half quarts more of the same fluid. The intestines were so thick and soft that handling them meant many ruptures so I determined at once to stitch the cysts to the abdominal wall and drain. It is needless for me to say that the hemorrhage encountered in the congested wall was something terrific, requiring more than a dozen forceps to control the bleeding points. This patient died at the expiration of about two weeks following the operation.

CASES III AND IV.

ACUTE CHOLECYSTITIS FOLLOWING TYPHOID FEVER.

This is a series of several cases seen during the past year all of which have symptoms in common so to speak; that is, all follow typhoid fever, some earlier than others.

Mrs. M., white, age 26, referred by Dr. Galbert, of Deepark, Louisville, with the following history: She had been running a rather mild temperature for several weeks, but for the past four days temperature had been normal.

Twelve hours prior to my visit she had been taken with chill; temperature 102, pulse 100, with severe pain in region of gall-bladder; muscles on this side were stiff and slight pressure gave pain. A diagnosis of acute cholecystitis following typhoid was made. She was sent to the infirmary and abdomen opened, the gall-bladder at once was found and a few adhesions were separated and the gall-bladder opened, and drained of about one pint of pus and thick tarry bile. Patient was able to return home in two and a half weeks from

time of operation, but since she and her husband were boarding she decided to remain for three weeks.

Mrs. M., white, age 38, referred by Dr. Spencer, of Jonesville, Va., with the following history: That after an attack of typhoid fever several years ago she had been having repeated attacks with her side in the region of the liver. On examination she was not only tender but a thickening could be mapped out here, so an operation was advised and after separating numerous adhesions the gall-bladder was freed and drained of about half a pint of thick tarry bile and mucous. This case left the infirmary in two and one-half weeks and returned to her home in Virginia.

REPORT OF A CASE OF MALARIAL PURPURA.

By M. L. RAVITCH, Louisville.

Though purpuric eruptions are quite rare in malaria, I had the opportunity to see a case in consultation several weeks ago in Lexington. The patient, a young man, age thirty, returned from New Orleans a week before he got ill. Two days before I was called he had developed an eruption on the face, hands and feet. He denied of ever having syphilis or taking any drug. When I saw him, his temperature was only 102. The night before I saw him he had a temperature of a little over 105. He was delirious.

Upon examination, I found the patient had slightly raised macules, the size of a dime and smaller and were of a purplish red color. They partially disappeared upon pressure but gave the impression of a purpura. No doubt but what the patient suffered from malarial purpura. I ordered a blood examination. Blood from the finger tip contained the tertian parasite.

I ordered quinine and arsenic internally and ointment of quinine externally. The patient, as I learned afterwards, ran a course of the disease of remittent type and six days after I had seen him, he was well enough to go about his work, only slight pigmentation marked the site of the eruption.

EXCISION OF RECTUM FOR CANCER; PRESENTATION OF PATIENT.

By G. S. HANES, Louisville.

The patient that I present to you to-night is 57 years of age. There is nothing in his family history that relates in any way to the condition that I shall report.

About two years previous to his operation he felt a small nodule on the posterior rectal wall just above the internal anal orifice. It was not long until he was convinced that this

tumor was increasing in size. He consulted a number of doctors who were by no means of concordant opinions as to the nature of his trouble. Fistula, hemorrhoids, tuberculosis, innocent tumor, syphilis and cancer were all suggested. On account of so much diversity of opinion among regular medical men he decided to try advertising cancer doctors. They all told him he had a suspicious growth that could be easily removed and as evidence of their skill they exhibited large numbers of preserved tumors which were products of their craftwork.

I saw him on November 12th, 1911. He had lost about 25 pounds, was very much constipated, had a great deal of pain and was very nervous. The tumor had grown down and involved the perineal floor between the coccyx and the anus. It had extended up on the posterior rectal wall about two inches and had encircled the rectum just above the internal anal orifice. There was almost complete obstruction and the tissues were broken down just posterior to the anus.

After several days preparation, he was operated on November 25th, 1911. An incision was made on either side of the tumor and anal structures from the coccyx forward to the urethral bulb. The tumor, together with the sphincter muscles, were separated from the surrounding structures; the levator ani was divided on either side and the rectum was dissected loose up to its junction with the sigmoid. The gut was divided at this point and a rubber tube three quarters of an inch in diameter was sewed into the proximal end of the bowel. The perineal floor was closed and the distal end of the tube projected below at the original site of the anus. Liberal drainage was provided for in the anterior and posterior angles of the wound.

He had comparatively no shock after the operation and but little pain. For the first three or four days drainage was profuse. The bladder was irrigated every day for two weeks with warm boric acid solution. In ten days he was walking about in his room and two or three days later he was out in the hall. He remained in the infirmary for almost a month. He is now in good health, has regained his weight and expects to resume his former occupation the first of next month. He has a normal desire to evacuate the bowel and can easily control the inclination until he is conveniently situated for the bowels to act. He has had no reason to take anything to regulate his bowels since early in January. In fact, he claims to have almost as good control over his bowels as he has ever had. He has been using a Wales bougie No. 5 every second or third day ever since the middle of December. There is no inconvenience in introducing the bougie except near the external

opening. At this point it is quite tight. On account of the contraction at the external opening I have advised him to use a No. 4 bougie.

The operation I did in this case was first done by Harison Cripps, of London, and it is known by his name. I decided to do the Cripps operation for two reasons: First, because it was undesirable to invade the peritoneal cavity as the operative field could not be made thoroughly clean and, second, because I did not want to disturb the normal relations of the sigmoid.

I feel confident we have all failed to properly recognize the important part the sigmoid plays in defecation. In this man there is no sphincter muscle of any kind to control the bowel. The control must be due to the sigmoid retaining the fecal contents till time for normal evacuation and the narrow canal through which the feces must pass. If the fecal contents in this case were thin and watery he would of necessity have more or less leakage.

The most important point to which I wish to call attention is that many of these tumors situated low in the rectum or involving the perineal floor and sphincters are not operated on for fear of loss of control of the bowel. And again if they are operated on the growth is not all removed for fear of producing incontinents. I am guilty of doing this very thing. I received word a few days ago of the death of a patient I operated on in 1908. He had a tumor involving the lower part of the rectum and the perineal floor. I operated and did everything I could to preserve enough of the muscle to insure, at least, partial control. In this effort I lost a possible opportunity to permanently cure my patient. By the method I practiced in this case no thought is entertained that frequent control may be possible by the activity of sphincter muscles so we are not deterred from making our operation thorough.

There is no place in the human body, I presume, where metastatic infection is less liable to occur than in the rectal cancer. If, then, these cases could be had when the tumors are young and liberal removal practiced there would undoubtedly be many cures effected.

Loss of control of the bowel or the necessity for a colostomy deters more patients from having rectal cancers removed than any other reason.

DISCUSSION.

Bernard Asman: Dr. Hanes is certainly to be congratulated upon the result he has obtained in this case. Any condition that renders necessary or justifiable the removal of the rectum is a serious condition, and merits the most careful study and consideration. Cases oftentimes come to us,

suffering from cancer of the rectum, in which the question of removal or non-removal is of the greatest importance, and one that we must try to determine by the extent of the involvement. Ordinarily, we believe that if the growth is limited to the bowel wall, it can and should be immediately removed. If there is metastatic involvement, removal will serve to palliate the condition and secure for the patient a much greater degree of comfort. Statistics show, however, that removal of the rectum in such cases is not followed by the result we desire. Sometimes, however, there will be found swelling of the inguinal glands, or the glands just in front of the rectum, but which may be purely inflammatory, and in such cases removal of the rectum is deemed advisable.

The question of the method of the removal is one that always comes up for consideration. I might say, in passing, that the operation described by Dr. Hanes, for excision of the rectum, is not a new one by any means. It has been known for two hundred years, but only in the past thirty years, and more particularly in the past eight or ten years, has it been done to any great extent. Kraske, in 1885, in what is frequently termed his epoch-making paper, declared that the rectum could be successfully removed by taking away a portion of the sacrum and coccyx, thereby securing room to get to the rectum and remove it radically. A great many surgeons then, and perhaps even now, considered this sort of surgery contraindicated in all cases, but in the past three years this has been abundantly proved to be a mistake.

The methods ordinarily considered are, first, the perineal (and the excision Dr. Hanes did is, of course, a modification of the perineal method); then the sacral operation advocated by Kraske; then the vaginal removal popularized by Murphy ten or fifteen years ago; then the abdominal method in cases where the growth is above the attachment to the peritoneum; then the combined operation in cases where the growth cannot be removed either by working entirely from above or entirely from below.

The patient presented is apparently in most excellent condition at this time. The removal of the growth has been radical, and I think he can reasonably hope and expect that it will not recur. That is always the chief consideration. Very often we think we remove these growths radically, with no possibility of recurrence, and yet in a few months or a year or two, the trouble will recur. Again, in other cases, where the condition is apparently hopeless and we naturally expect recurrence to take place, the patient goes along without any further trouble.

This modification of the perineal method, or whatever it may be termed, is indeed a very good one. The only objection to it that occurs to me is this: Since there is no mucous membrane from the point at which the gut was amputated down

to the anus, and the sphincters have been removed entirely, there must necessarily be a great deal of contraction. That contraction is already taking place is quite apparent from the fact that the patient is now using bougies in an endeavor to keep the channel open, and as time goes on I fear that considerable difficulty will be experienced in maintaining a channel of sufficient size to permit of easy defecation.

Another way of making such a patient comfortable, and which I have practiced in several cases, is this: After removing the growth completely, with the sphincters (as is always necessary if they are involved, or if there is not at least an inch of good sound bowel intervening between the sphincter and the lowermost margin of the malignant disease) then, instead of permitting this channel to carry off the fecal matter afterwards, provided an artificial anus in the colon at some convenient point, usually in the inguinal region. An artificial anus, carefully and properly made, at this point will give the patient a very fair degree of control, and of course he will then suffer no pain from contraction at the site of excision of rectum. Then the channel created by the removal of the bowel may be permitted to fill up entirely, if it will do so. It is possible, of course, that discharges may accumulate from time to time, resulting in a fistulous tract which will remain. Had the proximal end of the bowel, after the completion of the excision, been brought down, thus covering the raw surface, and sutured to the anal verge, it is quite possible that the contraction always incident to the formation of scar tissue might have been avoided.

W. C. Dugan: I wish to congratulate Dr. Hanes upon the most excellent result he has obtained in this case, and to place myself on record as advocating this operation. I think all cases of cancer of the rectum should be operated upon, provided there is no glandular involvement nor so much local infiltration as to make the operation inadvisable. I think the doctor was correct in forgetting, for the time being, that there were any sphincter muscles, and taking out all of the muscles and the perineal floor. It is an operation that requires great care, but even if the perineal cavity should be opened, not much risk would be entailed, as it could be sutured up and taken care of in that way. The great danger here is from closure of the fecal fistula, because it is nothing more than that, and it must be cared for faithfully by the patient. However, this man seems to be very intelligent, and I believe he will be able to meet the indications by the introduction of a bougie.

I believe that every tumor of the rectum should be examined and, if found to be cancerous, operation performed. Not long ago I was called to examine a woman for rectal trouble and found a classical fissure of the rectum. She was given an anesthetic, at her home, and the rectum dilated.

At the upper end of this fissure, contrary to the usual condition we find there, was a tumor which I pronounced malignant, and advised excision of the rectum, which was accepted. After removing the tumor, from its appearance I thought I had made a mistake in my diagnosis, although it had a malignant feel. I submitted the tumor to Dr. Allen who, as soon as he looked at it, said it was a fibroid tumor and not malignant, but his report showed that it was not only malignant, but very malignant. This woman was operated upon in October, and a few days ago when I saw her she was the picture of health, and was able to go anywhere without the rectum giving her any trouble, either from gas or fecal matter.

In connection with Dr. Hanes' report, I would like to ask him what he would think of taking a flap from each buttock, passing them into the space that was left and attaching them to the rectum. I believe this would aid materially in preventing the closure of the channel.

F. T. Fort: I believe that, where we have a fistula, as in this case, without the greatest care on the part of the patient closure will take place and an artificial anus will have to be made elsewhere.

Upon looking at the line of this incision, I wondered whether an incision from one tuberosity of the ischium to the other would not have resulted in less contraction, and caused less trouble in the introduction of a bougie to keep the channel open.

I would like to ask Dr. Hanes whether there is any involvement of the prostate gland and if he removed any portion of it.

G. S. Hanes, (Closing): Microscopical examination on this tumor, made by two of our best pathologists, show it to be a typical adenocarcinoma.

Answering Dr. Dugan's question I will say that I have no knowledge of anything having been done along the line of his suggestion. The fistula can be easily kept open in its upper extremity; the contraction is lowered down. In regard to the possibility of this tract healing and an inguinal opening having to be made, I hardly think that can occur as the patient has been passing the bougie since January 1st and it is done with as much ease now as it was done at first. A great many of these operations have been done and I never heard of serious trouble from this source.

The prostate was not involved and was not taken out. It is not at all difficult to remove it at this time.

As regards metastasis I will say that we should all bear in mind the important fact that metastasis seldom occurs when the cancer is located in the gut below the peritoneum. It is for this reason that tumors located in the rectum are unusually favorable for operation.

One of the chief reasons for patients hesitating in having rectal cancers removed is the fear they have in being unable to control the bowel.

The dread of incontinence is greater than all things else. No doubt, in many of these cases, an opening could be made in the left inguinal region and fair control established, but it is difficult to persuade patients away from the prejudices they have against this kind of procedure.

This method of operating, as I have said, is new to me so far as my personal experience goes. I shall watch these cases with a great deal of interest and if nothing in the nature of extraordinary complications arises I will feel much more at ease when I have similar cases to deal with in the future. And I believe I will be able to do a great deal more for my patients.

ALCOHOLICS.

(CASE REPORTS.)

By EDWARD W. STOKES, Louisville.

Mr. M., age 51, retired merchant; referred to me by Dr. C. O. Neff.

Admitted to Sanatorium September 7th, 1910. History, a chronic drinker for twenty years. He had suffered from hallucinations at times, for two years; marked insomnia and but little appetite. The amount of alcoholic stimulants this patient was taking was one to two quarts of whiskey and many beers in each 24 hours.

Treatment first day, or 24 hours: Patient put to bed and given the following dose every three hours:

Fld. Ex. Poke Rootmv.
or Water Shamrock, or
Tinct. Buck Beanmxxv
or *Meyanthes trifolia*.
Fld. Ex. Ergotmv
Fld. Ex. Gentianmxxv
M. Ft. sol. Dose No. 1.

Also Tinct. *Passiflora incarnata*, drachms 1, (one dose) every two hours. At bed time he was given two (2) improved c. c. pills. Patient was given a hot bath for 15 minutes before retiring.

Whiskey was given when called for on an average of once an hour. About midnight he was given sulphonal gr. xv. Rested but little first night.

Second day treatment. The same as first day but with this difference: at night he was given three (3) c. c. pills, and whiskey about every two hours and occasionally a beer as called for by patient. Patient had a restless night, sleeping only about three hours.

Third day treatment. Same as preceding days, except tonic was given only every four hours, and while patient did not now ask for whiskey he would drink it when proffered him, about every three hours, but complained that he could not "take it well as it made him sick." What was taken he retained, that is—

his nausea did not lead to vomiting. Stomach lavage in all cases when needed.

Fourth day treatment. Same as in preceding days but patient now refused all forms of alcoholic stimulants, and at times had hallucinations. On the 5th day I advised his wife to take him home, which she did, thinking home surroundings would help clear up his mind. On my order she gave him sulphonal gr. xv at 7 p. m., and he slept all night. On the morning of the 6th day he awoke with mind clear and has been so ever since. His general condition has constantly improved up to date and he has not taken a drink in eighteen months; and he tells me that he has never had the slightest desire for alcoholics. He is here to-night.

Mr. E., assistant manager of a Fourth Street store, age 40; a chronic periodical spree, and had to be sent home every week or two to get off a drunken spree. When he came to the Sanatorium in September, 1910, he was so drunk that he had to have help. He had a history of being a hard drinker for fifteen years, and was drinking from one to two quarts of whiskey a day when he was brought to me for treatment.

Treatment the same as in the preceding case and only varied as in every case to suit the demands of each individual patient. For instance: He had lost all desire for drink by the end of the second day and had quit calling for drink and when I found that it made him sick I did not give him any more.

Patient dismissed on the fourth day relieved, and he tells me that he has been attending to business every day for the last twenty months and has never had any desire for alcoholic stimulants of any kind. He is here to-night—ask him.

Mr. V., age 54; manufacturer; referred to me by Dr. Neff. Had drunk since a boy. For fourteen years he had been getting on sprees lasting for weeks at a time. He drank, on an average, about one quart of whiskey daily with many drinks of beer. When on these periodical sprees he always thought some one wanted to harm him—hence, he was always ready to fight.

He came for treatment January 19th. Same treatment was given him and he was dismissed on the fourth day after entering Sanatorium, relieved. He is here to-night and tells me that he has never had, to date, any desire for drink in any form.

Mr. D., former councilman and school trustee. A constant hard-drinker consuming seventy-five drinks a day. He was maudlin drunk when he came for treatment and had been so for so long a time that his friends thought that he was losing his mind.

He was admitted October 20th, 1911, and dismissed October 24th, four days later.

While he was diabetic at time of treatment, he has since gained 12 pounds in flesh and has worked every day and is sober and he says that he has never taken a drink neither has he the least desire for it. His treatment did not differ from the others.

Mr. R., age 44; Central City, Ky. Referred to be by Dr. W. C. White, March 9th, 1912. He had been drinking for thirty years. He had to be hauled home maudlin drunk every few days, but never had delirium. He did not think he could be relieved in five days but came to stay as long as he wanted to, in order to satisfy himself that he was well.

This is the privilege of all patients who come to my Sanatorium, but this man is about the only one who wanted to stay longer than five days.

He stayed nine days, but did not take treatment but four days, after the fifth day he declared that he had no desire whatever for any form of alcoholic stimulants—though before he took the treatment he was spending \$40.00 per month for drink. At his leisure one day he figured he had drank forty barrels of whiskey in the thirty years.

More than eight months ago I mailed letters to every physician in Louisville, New Albany, Jeffersonville and many other cities throughout the State, inviting them to see the treatment given. Some did me the honor to come and see it.

In treating alcoholics, I believe with Hare of Philadelphia, that we have no disease to deal with. Neither do I believe the tendency to consume alcohol to be an inheritance. And with Hare I believe it is a habit, and in many cases a habit that has produced degeneracy that permits the habit to exist.

In treating this class of patients, for convenience sake, I ignore the classifications such as: acute, sub-acute, and chronic alcoholism, as I believe this classification has little bearing on the treatment given or the results obtained, only in very exceptional cases where some chronic organic disease has advanced to its last stage.

The classification I give is, alcoholics with delirium, and alcoholics without delirium. In the delirium type I push the sedative as the case may demand; where we have no delirium no sedative is given, except the tonic mentioned from which I get some sedative effect—enough for such patients; but not a very marked sedative effect do I claim for it.

It is not my object to deal with the etiology, symptomatology and the various types of alcoholism, as time will not permit. Suffice it to say—any Sanatorium of consequence will be sure to get all kinds and all types, from the quiet unassuming to the delirious type.

One interesting point about these patients is the tremendous capacity some of them have

for consuming alcohol. I saw one man drink a quart of whiskey in about 45 minutes, while he was making up his mind to take the treatment. A physician who does not see much drinking or is not constantly with the patient will scarcely believe you when you tell them of the enormous amount some put away and can continue to do so for years, and upon a physical examination show but few signs of the effects of it—usually an enlarged liver, not often cirrhotic, and some slight impairment of the digestive organs, and some patients suffer from insomnia.

In order to obtain the best results, I believe it is absolutely necessary for the patient to be kept under close observation and in an entirely different environment, made possible by placing the patient in a Sanatorium with trained attendant night and day.

When a patient comes to my Sanatorium he is usually in one of three conditions: He may appear to be fairly sober; he may be in a drunken stupor; or he may be delirious. He is assigned to an ordinary room without padded walls. He has an attendant—one capable of handling him without abuse. He remains in this room until he is well. If he wants a drink of whiskey (and usually does) he gets it. Remember, there is nothing so soothing to these fellows as a drink of whiskey. Of course, all the time he is calling for drinks, you can administer your medicine.

Now, coming to the vital question: What advantage has this treatment over the hypodermic method which is practiced by some of the profession? Just this—that it does away completely with the hypodermic needle and its possibility for harm. That it destroys all craving and desire for alcoholic stimulants. It corrects the nervous disorders; restores the appetite, and brings to the patient natural, restful sleep. It eliminates the crib, the padded and barred rooms. We have no such barbarous paraphernalia. It makes it no longer necessary for the patient to remain from three to six weeks in a sanatorium to get sobered up. It is no longer necessary to give hyosine, morphine or bromides hypodermically or otherwise, thereby eliminating the possibility of their habit. Hyosine given to alcoholics is a most dangerous procedure, even in the most skilled hands, and when continued for several days you will find the effect upon the nervous system is such that it will take your patient weeks to recuperate, and it has killed more alcoholics than it has benefited.

If you desire to make it necessary for your patient to remain weeks at your sanatorium, hyosine is the one agent that will do it.

Another dangerous procedure is the use of Turkish baths for hours at a time. These patients come to us over stimulated. Now, to

take these over-stimulated patients and place them in Turkish baths for hours, you make a grave mistake. The patient who comes out of this treatment alive is fortunate.

One potent factor in the treatment, is the trained attendant, and one who is reliable and competent. The patient's comfort must be anticipated. I can not imagine anything more horrible for these unfortunates, than after a debauch they come to and find themselves in straight jackets, or in padded cells, and not a human being in sight for hours; perhaps furnishing for whiskey. Dantes Inferno pictures no more horrible suffering. Don't ever make yourself believe that these inebriates are insane; they are human like you and know much of what goes on. I am sure you will agree with me that the humane way of treatment is the best.

I have relieved, permanently, ninety per cent. of the alcoholics that have come to me for treatment. These men you have seen to-night are living examples. The ten per cent. that is not cured, is that class of degenerates who have no incentive to do right by themselves or their friends and while relieved for the time being, will return to the old scenes of temptation and soon fall a victim again.

Usually when a patient takes this treatment, he leaves the Sanatorium with his nervous system in a normal condition, his appetite completely restored and he sleeps like a child, and with the old craving for booze entirely gone. You can trust him anywhere and not a drop of alcohol will he tamper with for he remembers the dangers of it.

When we stop to think how little medical science has contributed to the treatment of alcoholism, and how the old hypodermic treatment continues with hyoscyne, morphine and other such alkaloidal products, with their harmful effects, it is no wonder that a treatment of this kind creates comment and doubt in the minds of those who are loath to bid farewell to their old friend, the hypodermic syringe. Should you be in doubt, I ask of you to withhold your criticism until you have investigated this treatment and have seen more of its results like you have witnessed here to-night.

Medical science has contributed little new in the treatment of alcoholism in the last quarter of a century, until this treatment was given. Yet it has stepped forth in its mantle of glory and dealt a death blow to small-pox, yellow fever, malaria, diphtheria, typhoid fever, tuberculosis, and other dreaded diseases.

DISCUSSION.

J. Hunter Peak: While I do not treat this class of cases, I happen to know one of the men here to-night and since taking this treatment, I have sat by him at a banquet board, where liquor

was as free as water, and he had his glass turned upside down. I have been in Dr. Stokes' institution a number of times to see patients requiring surgical attention, and have seen him administer the treatment a number of times, although I did not know what it was as it did not concern me.

The essayist mentioned the fact that Dr. Neff had referred several cases to him, and as Dr. Neff is here, I would like to move that he be given the privilege of the floor in order to discuss this report.

C. O. Neff: Two of the men exhibited by Dr. Stokes here to-night are patients of mine, and were referred by me to Dr. Stokes. One of them I have known for about five years, and he was one of the hardest drinkers I have ever seen. At times he would drink until he became unconscious. Twice a week, for six or eight months before he was referred to Dr. Stokes, he would have haematemesis of a very severe type, and he was in bad condition in many other ways. He had palpitation of the heart, which seemed to be of nervous origin, as I could find no evidence of any organic lesion. On one occasion, during the illness of his wife, he drank two quarts of whiskey between seven o'clock one evening and six o'clock the next morning. He has often told me that his bar bill was from five to eight dollars a day.

The other man was also a hard drinker. I have known him a long time, and I have never seen such a change in any one as has taken place in this man.

I did not rise to discuss the treatment of alcoholism, because I do not know any more about it than the average practitioner, and usually refer such cases to the sanitarium for treatment. I was rather forcibly impressed by the results obtained in these two cases, because in cases which I have referred to other institutions, the craving for alcohol was not eliminated, as it seems to have been in these men. In one or two instances patients whom I had referred to sanitarium, after leaving the institution, became intoxicated before they got home. In the cases shown to-night these men were relieved of the desire for alcohol and have remained so up to this time.

Curran Pope: I wish to add only a few words to this discussion. We do not treat these cases at my institution. I know one of the men here to-night; in fact I have treated him, but was never able to do anything with him. I know that he was a very heavy drinker, and that since his recovery he has remained well, because I am physician to a great many of his relatives and in that way I have been able to keep in touch with him.

The treatment which the doctor employs is rather unusual but apparently very satisfactory. Of course, no one can speak definitely of a treatment of which he knows nothing, but he has certainly shown results here to-night, and the testimony of the patients themselves is enough to

make one realize that he is doing good work and should be encouraged in it.

Bernard J. O'Connor: I would like to ask Dr. Stokes just one question; that is, whether he uses any other drugs in connection with his treatment, anything in the whiskey, etc., and, if not, how does he explain the cessation of the desire for alcohol under this treatment.

Edgar W. Stokes, (Closing): Answering Dr. O'Connor's question, I will say that the formula as given really constitutes a bitter tonic and destroys the appetite for alcohol. No other drugs whatever are used. We simply give this tonic until they lose all desire for alcoholics. Once in a while we offer the patient a drink, as a test, to see whether he really cares for it or not, and almost invariably we find they have not the least desire for alcoholic drinks and will sometimes even beg us not to give them any.

I mentioned in the report the treatment employed in delirious cases, and how we put them to sleep. We depend a great deal upon elimination in this treatment, and think it does these patients a great deal of good. We usually give the patient two c.c. pills at night and three the next night. Of course, there are times when this will not produce the desired effect, and the dose is increased. Aside from this, no drugs are given other than those mentioned in the report.

COUNTY SOCIETY REPORTS

Nelson—The Nelson County Medical Society met Wednesday, June, 5th at 11 o'clock A. M. in the office of B. E. Gore.

There were present, J. I. Greenwell, New Haven; H. S. Harned, Boston; Charles McClure, Cox's Creek; J. H. Wells, Fairfield; S. B. Crume, Bloomfield; B. E. Gore, H. E. McKay, S. A. Cox, R. H. Greenwell and Hugh D. Rodman, Bardstons, and Drs. J. C. Mudd and W. T. Barnett of Springfield. The reading of the minutes was dispensed with.

Report of Cases.

H. E. McKay and B. E. Gore presented a man 61 years old whose right arm was caught by a circle saw while at work in a barrel factory on April 10th, last, and all of the muscles for at least two-thirds of the circumference were severed to the bone, three inches below the axilla; also severing the humeral arteries, veins and nerves, cutting off pulsation at the wrist entirely; the contraction of the muscles caused a large ugly gap. The doctors saw him in a few minutes, cleansed wound, ligated the vessels, closed the gap by pressure and took twenty-odd 20-day cat-gut sutures to close the cut. Slight suppuration ensued; no secondary hemorrhage and no unfavorable complications. To-day the wound is entirely healed and the man has a good and useful arm, with yet no wrist pulse, both the ulnar

and the radial arteries seem to be obliterated. So much for conservative surgery.

Charles McClure presented two large fatty tumors, one of which had to be removed from a man's buttock, near the anus, which passed up and compressed the rectum; this was removed under cocaine anaesthesia with considerable pain.

The other was removed from the muscles covering the scapula just where one's suspender passes over the scapula; this was removed under quinine and urea hydrochloride anaesthesia and was painless. In reporting this case Dr. McClure said that in future he would inject the quinia and urea from 10 to 12 hours before he did any cutting; he regards this as an ideal anesthetic in circumcisions.

Essays.

H. D. Rodman read a paper on "Abortion" which he defined as being the expulsion of the contents of the pregnant uterus from conception to the viable period.

H. E. McKay: I think that almost all of our abortions are due to disease of the uterus and its appendages. I use blackhaw as a preventative. In those cases who are in a habit of aborting I put them on black haw or the viburnum compound and keep them on it until the abortive period has passed. I also put her in bed about two weeks before the expected abortion and keep her there until we have passed the time of the former abortion.

Charles McClure: Dr. Rodman has read a good paper and covered the ground thoroughly, and I agree with him that hydramnios often causes abortion. I recently saw a case who was supposed to be about three and a half months pregnant, who was as large as she should be at full term; an abortion came on and there was so much water than everything about the bed was saturated. I believe that there was two or two and a half gallons of water.

S. A. Cox: A prolapsed uterus will hardly ever carry a foetus to full term. Prolapse should be regarded as an important cause of abortion.

B. E. Gore: I have seen three cases of abortion in the last few weeks, two in consultation and one in my own practice. It is not always easy to arrive at the cause of abortion. I do not think that abortions occur as often as some authors state.

H. E. McKay: I do not believe that any kind of tampon should be used as a prophylactic measure. I believe such treatment would cause abortion.

S. B. Crume: While in New York recently I saw a case treated to produce an abortion; the tampon was used and used continuously until the desired effect was obtained. If I wanted to prevent an abortion I would not use any irritant about the os or cervix.

Hugh D. Rodman, in Closing: I am glad to

have elicited some discussion. Discussion is the life of a meeting. I do not expect every one to agree with me, it is by honest difference that we are improved. More is often learned by a few words of discussion by each member than by a lengthy essay.

S. B. Crume read a good paper on "Cerebro-Spinal Meningitis," also reported a case which he had recently treated of that dread disease. Many questions were asked Dr. Crume about the withdrawal of the spinal fluid and the introduction of the serum. In order to answer all Dr. Crume asked one of the doctors present to expose his spine and he demonstrated on this spine this operation, which was very interesting and instructive and was worth a good deal to all who saw it.

The visiting doctors were entertained at dinner at the Newman House by the Bardstown doctors. At the conclusion of the discussion we adjourned, a good meeting to meet again on Wednesday, September 4th, 1912.

HUGH D. RODMAN, Secretary.

Pendleton—The Pendleton County Medical Society met at the Day House in Falmouth, on Wednesday, June 12, 1912, with the following members present: P. N. Blackerby, O. W. Brown, N. B. Chipman, H. C. Clark, C. H. Kendall, W. A. McKenney, T. C. Nichols, John E. Wilson, J. Ed Wilson, K. B. Woolery.

The meeting was called to order by Vice President, O. W. Brown.

We had a report of clinical cases by some of the different doctors, which were freely discussed by many of the members present.

O. W. Brown read a paper on "Hernia," which was pretty thoroughly discussed.

P. N. Blackerby read a paper on "Myocarditis." This proved to be a very good paper, and it elicited thorough discussion.

This being all of the essayists ready that were present, this closed the papers and their discussion, and as the hour was growing late, a motion to adjourn was entertained by the Chair, and we departed to our various homes to meet again the second Wednesday in next month.

W. A. McKENNEY, Secretary.

Washington—The Washington County Medical Society met in Springfield on June 12th, at 2:30 P. M., with the following physicians present: J. Hunter Peake, of Louisville; McClure, Cox's Creek, Nelson county; J. N. Shelan, Ray, Mudd, M. W. Hyatt, Crume, Hatchett, Barnett and Hopper, of this county. Bernard Asman, of Louisville, was expected but was unable to be present.

J. Hunter Peake, who was to lead the discussion of Dr. Asman's paper, was asked to give us a lecture on any subject he chose. He took for his subject "Misplaced Kidney." He handled it in a way that was most interesting and very instructive. Discussion followed by Drs. She-

han, Hyatt, Hopper, McClure, and by Dr. Ray at some length, and by Dr. Peake in closing.

W. T. Barnett and **W. W. Ray** are on the program for July.

President Crume thanked the visiting physicians for their presence and the part they took in the exercises, and invited them to attend our meetings whenever they can.

J. H. Peake has been with us on several occasions and we are always glad to see him. We always look for something good from him and get it.

J. H. HOPPER, Secretary.

BOOK REVIEWS

A Treatise on Tumors, by Arthur E. Hertzler, M. D., Ph. D., published by Lea & Febiger, Philadelphia-New York, 1912.

This Treatise embodying the experience of many years gained in the operating room and observation of labor, and the information gathered from libraries, combines them in such a way as to be of practical use. It is a competent guide to the recognition of tumors, being extensively illustrated with accurate descriptions of the pathological specimens presented.

The Practitioner in General Medicine, Volume 1, General Medicine, edited by Frank Billings, M. S. and M. D. and J. H. Salisbury, A. M., M. D., Series 1912.

This Volume discusses immunity and vaccine therapy, infectious diseases, including acute anterior poliomyelitis, diseases of the lungs and pleurae, diseases of the circulatory organs, diseases of the arteries, blood, ductless glands and kidney.

Volume 2, edited by John B. Murphy, A. M., M. D., LL.D. This volume deals with anesthesia, new instruments, operative technique, wound healing and pathological interventions, tetanus, tumors, the bones, the face and the mouth, abdominal surgery, taking up incisions, wound closures, drainage, complications, peritonization, the vermiform appendix and pancreas. These two volumes are full of practical up-to-date matter for the use of the busy man.

Diseases of Genito-Urinary Organs and the Kidney. By Robert H. Greene, M. D., Professor of Genito-Urinary Surgery at the Fordham University, New York; and Harlow Brooks, M. D., Assistant Professor of Clinical Medicine, University and Bellevue Medical College. Third Revised Edition. Octavo of 639 pages, 339 illustrations. Philadelphia and London, W. B. Saunders Company, 1912. Cloth, \$5.00 net; Half Morocco, \$6.50 net.

This volume of 630 pages is a complete presentation of the problems arising from the discussion of the Genito-Urinary system. In a prac-

tical way, it deals with endoscopy, cure of instruments, preparation of patient, chemical and microscopic examinations of the urethral evadate, ocular manifestations of renal diseases, tuberculosis, malformations and displacements, surgery of the kidney, conditions of the bladder, tie and epididymis and neuroses of the sexual male and female urethra, prostate gland, testorgans.

Psychotherapy. including the history of the use of mental influence, direct and indirectly, in healing and further principles for the application of energies derived from th mind-to the treatment of diseases, by Jas. J. Walsh, M. D., Ph. D., published by D. Appleton & Company, 1912.

This interesting volume takes up the history of psycho-therapeutics, discussing unconscious psycho-therapeutics, general remedies and suggestions, exaggerations, pseudo-science and mental healing, quackery, and mind cures, nostrums and healing power suggestions, influence of personality, therapeutics and faith cures. Under the head of general psycho-therapeutics, are discussed influences of the mind on the body, brain cells and mental operations, unconscious cerebration, hypnotism and kindred subjects. A section is devoted to special psycho-therapeutics dealing with the digestive tract, cardio therapy, respiratory diseases, psycho-therapeutics of the joint and muscular system, gynecological and obstetric psycho-therapy. Under the general subject of disorders of the psyche are discussed, psychoneurosis, disorders of the mind and disorders of the will.

Differential Diagnosis.—Presented through an Analysis of 385 cases. By Richard C. Cabot, M. D., Assistant Professor of Clinical Medicine, Harvard Medical School. Second Edition. Octavo of 764 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1912. Cloth, \$5.50 net.

This well-known work in the second edition which brings it up to the present, scarcely needs comment. Under the heads of regional pains, each pain is made the basis for exhaustive and clear discussion and differentiation of the conditions causing it. Following the same ideas of differentiation, there are discussed convulsions, weakness, cough, vomiting, hematuria, dyspnea, jaundice and nervousness.

"Cyclopedia of American Medical Biography," by Kelly. Volume One and Two make a common and deserve a place in the physician's complete historical review of the best known medical brary.

"The Friends of the Insane," by Baynard Holmes, M. D., Lanet-Clinic Publishing Company press. Price \$1.0.

Physiology.—A manual for students and practitioners by A. E. Guenther, Ph. D., and Theodore C. Gemthier, published by Lea & Febiger, Philadelphia-New York. This is a brief compass of those facts of which medical students should be familiar in order that they may pursue the more advanced courses of the medical curriculum.

Physiology of Faith and Fear, Or, the Mind in Health and Disease, by W. S. Sadler, M. D., published by A. C. McClurg & Co., Chicago.

THE FORUM

TO THE EDITOR:

On June 6th, at Atlantic City, during the meeting of the American Medical Association and following a symposium on anesthesia, the National Society of Anesthetists was organized. Prof. Yandel Henderson of Yale, Chairman of the commission on anesthesia of the A. H. A., occupying the chair, those assembled for the symposium acting as a committee of the whole, proceeded to organize, and elected the following officers for the year 1912-1913:

President, James T. Cwathmey, of New York; Vice Presidents, Charles K. Teter, of Cleveland, F. H. McMeekhan, of Cincinnati, Yandel Henderson, of New Haven; Secretary, William C. Woolsey, 98 Lafayette Ave., Brooklyn; Treasurer, Harold A. Sanders, of Brooklyn.

The constitution and by-laws were ordered to be drawn by the executive committee and submitted to the society at its next meeting for adoption; all names submitted for membership, if qualified in the estimation of the executive committee, shall be considered as charter members if presented within a period of sixty days and accompanied by the levied due of three dollars.

The National Society of Anesthetists in this notice, calls all those who are actively interested in this work, to join its ranks and assist in developing the subject of anesthesia to greater perfection and more uniform safety.

WILLIAM C. WOOLSEY, Secretary.

Petrogen and Creosote Petrogen. Petrogen is essentially a mixture of liquid petrolatum and soap liniment and does not widely differ from the preparation petrolatum saponatum liquidum (petrox, liquid petroxolin) N. F. As an improvement on creosote petrogen the following formula has been proposed for creosote petroxolin for the National Formulary: Creosote 20 Gm., oleic acid 5 Gm. and liquid petroxolin 75 Gm.—(Jour. A. M. A., Feb. 3, 1912, p. 365).

EDITORIAL

CRIPPLING THE STATE LABORATORIES.

THE JOURNAL is asked to make an appeal to county societies, health officials and the profession of Kentucky, for such discussion of the matter at future meetings as will insure greater care in the preparation of specimens sent in to the official laboratories for analysis. In spite of the fact that detailed instructions as to the collection, preparation and shipment of the various kinds of specimens accompany all containers sent out from both the Chemical and Bacteriological Laboratories, and the absolute necessity of having the name and address of the sender or patient as the case may be, plainly written on the label, is constantly emphasized, scarcely a day passes that specimens do not come in which it would be a waste of time to examine on account of carelessness in preparation or lack of necessary information on the label. For instance, many specimens, often a dozen or more in a day, are received with no name, address, or postmark even, to indicate the sender, and, a few days later, after the specimen has spoiled or cannot be identified a complaint is made because no report of the examination has been received. Again, diphtheria specimens are sent in tubercle or hookworm containers, or vice versa, and thoughtless and inexperienced people seem to think that anything which will not leak is good enough for water.

Special retainers for all purposes, with full instructions, will be gladly sent without charge to all who apply for them, but, in view of the urgent need for greater care in the collection and preparation of specimens, the State Board of Health asks that the subject

be given a prominent place on the program of coming county society meetings, and that, with the various kinds of containers before them, proper methods of preparation be demonstrated by members who have given special attention to it.

THE ANNUAL SCHOOL FOR COUNTY AND CITY HEALTH OFFICERS.

In the light of the future welfare of the people probably no more important meeting has ever been held in Kentucky than the Annual School for County and City Health Officers, at the Armory Building, Louisville, July 8, 9, and 10. Partly because the law makes attendance compulsory with all necessary expenses paid by the county or municipality, and still more, because of the interest aroused by the program, the health officer of nearly every county and city in the State was present and took part in the proceedings, as did the county judges from many counties.

Hon. Muir Weisinger, Judge of Jefferson County Court, which employs a health officer to devote his entire time to the duties of his office at a salary of \$2,500.00 a year, furnishes him a well equipped laboratory, bacteriologist and stenographer, and appropriates \$10,000 a year for health work in the county outside of the City of Louisville, and which gave the use of the armory and made a special appropriation to meet the local expenses of the School, delivered an eloquent and most appreciative address of welcome, in which he extolled modern health work as exemplified in his own county. Governor Edward J. McDermott presided over and opened the first formal meeting with an able address on "Conservation of Health and Life in Kentucky."

The chemical and bacteriological laboratories and their operators, and those of the City Board of Health of Louisville and of

Jefferson County, were in large part removed to the armory and every phase of their work was demonstrated from hour to hour. The heads of the various departments and members of the State Veterinarian and his assistants and many County and City Health Officers took an active part in the demonstrations often illustrated by stereopticon and moving pictures.

Outside of these health workers and related forces in our own ranks, Professor Wyckliffe Rose, Washington, D. C., Executive Secretary of the Rockefeller Sanitary Commission; Drs. J. N. Hurty and Owen, Indianapolis, respectively Secretary and Assistant Secretary of the Indiana State Board of Health; Dr. J. W. Pettitt, Ottawa, Illinois, Superintendent of the Illinois Tuberculosis Tent Colony; the Kentucky State Tuberculosis Commission; Dr. John McMullen, Washington, D. C., U. S. Public Health and Marine Hospital Service; Professor Fred Mutchler, Bowling Green, Science Teacher in the Western Kentucky Normal School; Hon. Barksdale Hamlet, Frankfort, State Superintendent of Public Instruction; and Mr. John B. McFerran, Louisville, School Expert and Humanitarian, had leading parts on the program in their special lines and rendered invaluable assistance in the instructions and demonstrations.

By unanimous vote, before adjournment, the State Board of Health was requested to arrange the program to cover a six days' course of instruction next year, and all in attendance left with promises of more effective work and better health conditions in their respective jurisdictions as the result of the meeting, no others seeming more impressed with its possibilities than the county judges.

FREE PASTEUR TREATMENT FOR RABIES.

On account of the unusual prevalence of rabies in widely separated sections of the State, coupled with the fact that the preventive treatment for persons bitten by rabid animals in private Pasteur institutes is so costly as to put it beyond the reach of most of those who need it, the State Board of Health sent the State Bacteriologist on to Washington to investigate the methods of its administration and to arrange for the free treatment of any person in Kentucky who applied for it. The U. S. Hygienic Laboratory agreed to furnish the serum without cost, but only upon condition that it would be used in the Laboratory of the Board, and that copies of all records of treatment, and the results, would be filed in Washington. From the time this arrangement was perfected there has never been a time when cases were not under treat-

ment, the cases coming from counties representing every part of the State.

The treatment covers a period of twenty-one days, the injections which are practically painless, being given daily, and are absolutely free alike to rich and poor. The Laboratory people assist patients in finding board, which costs from three to four dollars a week, depending upon the taste of the individual. A number of colored patients have been treated, and for them board is less expensive. The serum is ordered by wire for each patient in order that it may be fresh, and delay can be avoided if the Laboratory can be advised in advance when cases will arrive for treatment, which of course, should be as soon as possible after they are bitten.

Only the brain of rabid animals, preserved in glycerine, without the use of other preservatives or disinfectants of any kind, should be sent in for examination. Often the head, and a few times the entire carcass, of dogs arrive at the Laboratory in such an advanced state of decomposition as to be wholly useless for any scientific purpose. Without careful attention to instructions as to these details, as true in sending in water and all other specimens for analysis, every phase of this life-saving work is hampered or goes for naught.

The rabic work is entirely in the hands of Dr. L. H. South, State Bacteriologist, and all inquiries and correspondence on the subject should be sent to her at Bowling Green.

THE PREVENTION OF BLINDNESS.

At the recent meeting of the American Medical Association at Atlantic City, the attention of the House of Delegates was called to the rapid increase of trachoma and other communicable eye diseases among immigrants arriving in this country, in various centers of population, and especially in the Appalachian Range of Mountains, and the U. S. Public Health and Marine Hospital Service was officially asked to assist state and local boards of health in a broad study of the cause of such diseases and their recent increase with the view of restricting their further spread.

Because of the self-sacrificing work reports of Miss Linda Neville and Dr. J. A. Stucky, both of Lexington, who had visited and held clinics in Knott and Letcher counties, and had brought many patients to the hospitals at Lexington for free treatment, the State Board of Health of Kentucky was advised as to the need for prompt action, and ours was the first State to request the cooperation of the National Government. In response to this, Dr. John McMullen, a distinguished member of the above named Service, who has a large experience with trachoma and similar eye diseases in dealing with immigrants at

the port of New York and in foreign countries, was detailed for duty in Kentucky and came on to deliver an address on the subject before the School for Health Officers in Louisville and to get in touch with the health officials from the most severely affected counties.

After conference with the Board, Drs. Stucky, Duke and others, Dr. McMullen worked out an itinerary to include the counties of Knott, Perry, Leslie, Clay and probably others, of which due notice will be given to the profession and health officials. A report received from Dr. McMullen just as this goes to press gives the information that he has almost completed his investigations in Knott county, finding from 2 per cent to 4.5 per cent, of infections from trachoma in many of the schools, representing every stage of the disease from the acute form to the most hopeless and incurable conditions. Our readers will be kept advised of Dr. McMullen's work as it progresses, and the results of his investigations and his suggestions as to restricting the spread of this and other contagious eye diseases will be given the widest publicity through a special Bulletin of the State Board of Health.

THE MASTER HAND.

The Atlantic City meeting of the American Medical Association was one of the most successful it has ever held. The arrangements were more than unusually complete excepting that the scientific exhibit was sadly misplaced. The members and delegates in attendance all recognized and yielded tribute and admiration to the master hand, which quietly and unobtrusively guided and controlled everything. We have had occasion in these columns to pay tribute frequently to the Editor of the greatest Medical Journal ever published, but there has never been a time when we have so greatly realized his ability to organize and control, feeling as we do that there must be a head to everything. In the far-seeing, wise, counsel-taking hand, who will coordinate the activities and steer the forces of every organization, we feel that the American Medical Association is to be especially congratulated as Dr. Geo. H. Simmons is at the helm. Such power as he wields would be dangerous in the hands of a smaller man or a self-seeker, but he stands out in the limelight as one of the few men who might control the destinies of this great organization, who are at the same time large enough in their conceptions and ideals to control it wisely. It is the greatest pleasure to pay this tribute to this benefactor because his control of the situation at Atlantic City was so quiet that it was unnecessary for him to appear publicly at

any time. The officers selected are a tribute to his wisdom and the measures for future work adopted and indorsed at his suggestion, or with his approval, give promise to a greater effectiveness to the great Association of which he is the real head. We are sure we voice the views of the profession of Kentucky in expressing the wish that Dr. Geo. H. Simmons may long continue in such health and activity as to be able to keep his hand on the throttle and push the whole medical profession forward as only such a man as he can do.

ATLANTIC CITY.

The meeting of the American Medical Association, at Atlantic City, was a great success. Dr. Jacobi's address was unusual in character and of such great economic and moral importance that we take pleasure in reprinting it as the leading article in this issue of our JOURNAL.

A timely treatment of the midwife question is cordially commended to our profession as worthy of most careful consideration. We desire to especially commend to the profession Dr. Jacobi's statement of the superiority of maternal nursing over any artificial nursing. It is with some surprise that we note in the current issue of the *Journal of the American Medical Association*, the statement "Some may, however, be not quite so optimistic as he as to its universal practicability," which statement could only be written by one who has not followed Dr. Jacobi's teachings on this subject through many years of practice. We believe that in practically every case where artificial nursing is resorted to that a mistake, both moral and economic, is made. We are confident that Dr. Jacobi's teachings has the indorsement of practically every physician in Kentucky and we trust that part of this article will be read by their family physician to such mothers as need it.

The scientific program was excellent and the registration of 3598 was an excellent one.

Among other important proceedings of the House of Delegates, was the splendid detailed reports of the Board of Trustees and Council on Medical Education and Health and Public Instruction. The splendid report of the Council on Medical Education merited the unanimous vote of approval extended it. Several important amendments to the By-Laws were adopted. Some of these provided for the recall of any officer or member of a Committee or Council by a two-thirds' vote of the House of Delegates. Rules of procedure for Judicial Council was approved, and this Council was requested to investigate the subject of secret division of fees and the giving of commissions, and the matter of contract practice, and recommend such action by the

House of Delegates and the constituent associations as will remedy existing evils. In the Tri-Annual re-apportionment, Kentucky retains four delegates.

Louisville and Minneapolis were the contenders for the place of the next meeting, and in spite of our most poetic of invitations to Kentucky by Dr. Curran Pope, Minneapolis won out by a close vote. The cordiality of the invitation to Louisville, however, produced a decided effect and it seems apparent that within the next year or two, Kentucky shall have the opportunity of welcoming the parent Association.

THE NATIONAL RED CROSS.

The Editor of this JOURNAL was the Chairman of the Committee to confer with the National Red Cross, and his report will be found on page 1896 of the *Journal of the American Medical Association*, as follows: Amendment to the By-Laws for this Committee was unanimously adopted by this Association and we feel confident that this great work will be undertaken by both the Red Cross and the American Medical Association with renewed zest:

"To the Members of the House of Delegates of the American Medical Association:

Your Committee to Advise with the National Red Cross has the honor of reporting that through its Chairman, three conferences have been held with the officers of that organization—one in New York and two in Washington.

It is a pleasure to testify to the grasp, efficiency and usefulness of the heads of our Red Cross, and to pay a special tribute to its presiding genius, Miss Mabel Boardman.

The first problems presented by the Red Cross to your Committee were, "How may we organize an effective medical force throughout the country which may be available without delay in case of a local disaster?" "When medical services are volunteered to the Red Cross, how may it determine the reputability and competency of the volunteer?"

The opportunity offered to our profession for life-saving work of the highest character seems manifest. If in times of great disaster a wise executive committee of the Red Cross right on the spot is already empowered to act and then report to the general officers at Washington, its work will be far more effective than the present somewhat haphazard method of organization following newspaper or other more or less roundabout notification. The good work of the Red Cross under this system has been due to the genius and initiative of its general officers and it is their desire to diffuse the responsibilities as well as the opportunities for good into a great organiza-

tion actually national that will reach into every nook and corner of the country where disaster may come of such character that it demands more than local assistance. A disaster involving a remote mine in Tennessee or the Dakotas, a railroad wreck in Arizona, a schoolhouse fire in Ohio, a factory holocaust in New York, or a flood in Kansas or Arkansas should have in its own vicinity an organized force ready to spring into active operation instantly and take the initiative in relief work, which is frequently the most important part of the whole Red Cross campaign.

Your committee therefore recommends: (1) that a standing committee of three on Red Cross medical work be constituted by an amendment to our By-Laws, one of whose members shall be appointed by the President on the nomination of the Surgeon-General of the Army, and one on the nomination of the Surgeon-General of the Navy; that the third member of the committee, who shall be its chairman, shall be appointed by the President of the Association and nominated to the Red Cross as the representative of this Association on its Relief Board; (2) that the necessary expenses of this Committee, not to exceed \$500 annually, be paid by the Board of Trustees; (3) that this Committee shall have advisory supervision over state and county committees and shall be empowered to act for the Association in matters involving medical personnel in times of disaster, provided that it shall not be authorized to involve the credit of the Association without express authority of the House of Delegates; (4) that this Association recommend to its constituent associations that they constitute similar committees of which the State Secretary shall be Chairman; and a county committee for each component society of which the District Councilor and the County Secretary shall be ex-officio members; (5) that such state and county committees shall have similar duties to the national committee in their respective jurisdictions, and shall be authorized to cooperate with the lay, nurses, finance and other committees of the National Red Cross in carrying out their functions.

It will, we feel sure, be readily seen that such a vast organization as is contemplated in this report, involving the formation of thousands of locals all over the country by the National Red Cross, will, if successful, be forced to do something to keep its hand in, so to speak, and your Committee has suggested the possibility of such an organization of existing hospitals and nurses' training schools and other public health forces as will best train them as agencies for the protection of life in times of war or national disaster while they are actually responding to the constant calls of the tens of thousands of unnecessary

and preventable deaths in the country each year from preventable diseases, from faulty sanitary and housing conditions, from industrial and other violence. This would involve the formation of a central organization supervising training-schools for nurses with similar functions and powers of moral suasion as our Council on Medical Education. It would involve, eventually, at any rate, the coordination of all those forces working publicly for the prevention and cure of ill health and resulting loss of life. It would involve, in due course of time, such local cooperation with the local authorities and the people as would lead to the establishment in all centers of population, at least in all county seats, of hospitals whose function would not be merely the cure of diseases but which would be real centers from which should emanate everything which could help the people of that community toward right living.

Gentlemen, this may seem idealistic. No ideal can be too high either for the American Medical Association or the National Red Cross which can work to the welfare, health and happiness of the American people in peace or in war. It will involve hard, prolonged work, but the results to be accomplished are so vast that it must be worth while, and American medicine has accomplished too much to turn from any opportunity to do more. Until the profession and people of the United States have at least made its cities and its rural communities as healthy as Colonel Gorgas and his associates have done in pestridden Panama, we have an opportunity which we may not neglect.

Respectfully submitted,

A. T. McCORMACK, Chairman.

CHARLES A. L. REED,

MILES F. PORTER,

H. L. E. JOHNSON.

This report was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

The minutes of the previous meeting were read and approved.

PELLAGRA.

A letter from Dr. C. H. Lavinder, a past assistant surgeon of the United States Public Health and Marine Hospital Public Service, at Savannah, Georgia, is worthy of special attention to everyone interested in the treatment of Pellagrins. The Marine Hospital, at Savannah, Georgia, is receiving and treating, free of charge, a limited number of male pellagrins. Congress has authorized the use of this Hospital for the treatment of a certain number of male pellagrins, all colors and ages, excepting infants, free of all charges except transportation to and from the Hospital.

Under this authority Sergeant-General Blue has directed Dr. Lavinder to admit these cases and several are there at present taking the treatment. A good hospital, and every possible care without expense, is offered these cases. The desire of the Public Health Service is to have a number of cases in their Hospital for scientific observation and treatment. Any physician who has patients who would be interested in this opportunity are requested to correspond with Dr. Lavinder.

KENTUCKY.

In compliance with numerous requests, we are republishing the poetic invitation by Ex-Governor Willson, of Kentucky, to the American Medical Association, to meet in Kentucky:

"Know'st thou the land where the corn-tas-
sels bloom,
Where the mystical cock-tail exhales its per-
fume,
Where the high-balls sparkle with flavor di-
vine
And the 'schooners' sail fast 'neath the shade
of the vine?
Know'st thou that land, that beautiful
land?

Know'st thou the land where the Julep was
born,
Where the mint yields its breast to the spirit
of corn,
Where the ice strikes the glass with a musical
sound
And the straw shrieks aloud, when the bottom
is found?
Know'st thou that land, that beautiful
land?

Hear'st thou the call of the Blue-grass to
thee;
Come over the River, come Southward to
me,
Where a welcome awaits from Kentucky's old
boys,
Oh come to that Southland and taste of her
joys,
Oh come to that land, that beautiful
land.

Know'st not that land? Then thou art un-
lucky;
'Tis gallant, 'tis brave, 'tis hearty Ken-
tucky,
That calls from the River that flows to the
Sea,
Come Southward to meet us, cross over and
see,
Oh come to that land, that beautiful
land."

OPTOMETRY AND THE OPTOMETRISTS.

This is the day of insurgent and insurgency. Abuses, and in some instances crimes against the individual, the state and the nation are being corrected by that greatest and best of policemen, light; light into the dark corners; the light of publicity. That there are many things in every business, in every trade and in every profession to be corrected goes without saying and it seems as though Arno Dosch has selected as his particular point of attack, the abuse within and just without the pale of the medical profession, both in its regular membership and in those guerillas that practice their warfare upon the uninitiated and who prowl, hyena like into the precincts of specialty and legitimate medical work.

In an article, entitled "Eye Troubles and Eye Doctors," Dosch views a subject that is of vast importance to the layman and in my opinion, he takes the right view.

After consideration in a general way the great value of eyesight, he calls attention to the well-established fact, recognized by all competent physicians that accurate vision and properly balanced eyes are essential to not only the comfort, but oftentimes to the mental, nervous and moral makeup of the individual. Ill balanced sight, inaccurate or improperly balanced, oftentimes deprives the individual, not only of his capacity for making a living, but many times hinders him from exercising to the fullest, the capacities inherent in his makeup. For this and sundry other reasons, too many to mention, it behooves the laymen and the medical men as well, to be exceedingly careful as to who and how glasses should be adjusted and the troubles incident thereto corrected.

He draws very nicely a distinction between the optometrist and the eye specialist, who should be a thoroughly well trained physician. That anyone were to attempt to simply fit glasses without a thorough comprehensive and detailed knowledge of the eye, its disease and the influence of health and pathological states upon the eye, is one of those marvels that are only explained by the fact "that there is money in it."

How many cases competent specialists can detail of the damage done by the incompetent, is doubtless difficult to enumerate.

But one must not forget that the medical profession in this specialty is not without its flaws. Untrained physicians, made specialists over night by some few weeks post-graduate course, is hardly the man to whom one should trust his eyesight, and in fact his suggestion, that hereafter State Boards license specialists only after a competent and ex-

haustive examination, would do much to undo the faults of the pseudo-specialist.

His final, conclusive suggestions are excellent, to-wit, that no one have glasses adjusted or their eyes examined save by a graduate physician, who has had thorough training in the *mechanical and pathological* states of the eye and that the patient only permit this examination to be made by men known to possess the necessary qualifications. These are the articles that are helpful to scientific men and scientific medicine and which will in the end drive the optometrist to qualify, if he wishes to follow out this work.

CURRAN POPE.

THE POOR MAN'S LUXURY.

When the thunder vibrates and the lightning flashes in its unguificent display from cloud to cloud; when the windows of heaven are opened and the mighty torrents of water drench the earth, and is gathered into brooklets, rivulets and finally into the majestic rivers of the country, few indeed realize that in plain, simple water, internally and externally, lies a power capable of so much good that it might, with perfect justice, be termed "the poor man's luxury."

Water distributed beneficently upon the surface of the land, not alone stimulates the seed to sprout, to push aside mother earth and luxuriate in the sunshine that grows crops and fills granaries to make a nation rich, but it also possesses the power, when properly used to bring about the same kind of stimulating effect upon the protoplasm of the human body. In all the range of medicine, it possesses the power of meeting more nearly the needs of the healthy and sick organisms than any other one remedial measure known.

While not in the least discrediting their measures and while fully realizing the benefits that may come from the use of chemical means from both the animal and vegetable kingdom, still how few realize that right at hand, in the clear, cold spring, or the more modernized faucet flows an agent that is capable of rejuvenating tissue and maintaining health. It is hard indeed to excel the invigorating power of cold water, especially where applied upon the cutaneous surface under pressure, as in douches, showers, etc. Every well built physique, every trainer, every athlete and every doctor ought to know that cold water is in itself the greatest and best tonic, and that in addition to affording a means to what Wesley has called "next to Godliness," it produces affects that increase vitality.

It is an exhilarating and stimulating bath of the Anglo-Saxon, and in this particular climate and in our strenuous age, it should be

employed by rich and poor alike, and oftentimes in place of the convivial cup or morn-ing "pick-me-up."

Among the interesting psychic attitudes of many human beings, is to be found Cold-Bath-a-Phobia, for in truth, there are few people who have sufficient courage, I might say, moral or physical, to use the cold bath. If the poor man used it oftener, he would pay fewer doctor's bills; he would feel good enough to drink less liquor, he would be able to do his work with more zest and he would, in all likelihood be physically, mentally, nervously, and morally, a better human being for his contact with "nature's own."

CURRAN POPE.

THE NEW OPIUM LAW.

Under official announcements, we are publishing correspondence from the Secretary of the State Board of Pharmacy. It is a pleasure to commend this law and urge its enforcement with our doctors. It prohibits, with large penalties, the sale of opium or opium products by doctors. This applies particularly to morphine. No reputable physician should sell any opium product in quantities, and it is a pleasure to commend the actual enforcement of this law to all of our profession.

A REMARKABLE BANQUET.

The Editor had the privilege of attending a remarkable banquet at Nashville in honor of Dr. J. A. Witherspoon, President-Elect of the American Medical Association. It was remarkable, not only for the excellent arrangements in every way, but as a tribute to this great man by his professional and business associates in Nashville. Looked at in the larger sense, it was as great a tribute to those who gave it as to the distinguished honoree. We feel particularly fortunate in securing a response to the toast "Man's Friend, the Doctor," by Hon. John T. Lelyett. This splendid tribute is worth the reading by every doctor and every doctor's friend in Kentucky.

Mr. Toastmaster, Our Honored Guest, and Gentlemen:

I would be less than sincere if I did not feel and express pride and pleasure in the opportunity given me to-night to add, however slight, a testimonial to our distinguished guest, and incidentally, to his great profession.

Our guest has lived among us many years. He has, by his superior talent, application, good qualities and unselfishness built up with us a great esteem and high character as a physician, and as a man, he has won our love and affection by his kind manliness.

He has, although in the front ranks, and

busy with a large practice, with sufficient gains close at hand, been unselfish enough to step aside to so accomplish himself as to attract the attention and secure the endorsement of the greatest body of physicians and surgeons on earth, the American Medical Association, and in receiving this honor, he has, in turn, reflected honor upon us who to-night represent his state, his city and his home.

It is fitting that a man of his professional eminence should live in Tennessee, and in its capital city, for here we live in the very shadow of the home of the nation's greatest chief, Andrew Jackson. And before the lives of any in this assemblage to-night, this city was the noted rendezvous of men whose fame and deeds have been pictured in the halls of national fame, and in all of the times since her infancy, whether in acts of civic virtue, in professional attainment and achievement, or in the real strife, where the roll of drum inspired to battle array, Nashville has been the pivotal-spot of the great and justly named Volunteer State.

I congratulate our talented guest to-night upon his success. I rejoice in it as a fellow citizen and friend. I congratulate his state and city upon this justly earned triumph, and I congratulate his brother physicians on this stride in the march of this great and progressive profession.

It is a profession which comes close to the bodies, minds and hearts of mankind. It has been nourished and has grown upon the trust and confidence of the world, and deservedly so.

From the beginning, doctors of medicine, of learning and of law were ever seekers after truth, and they have in the medical profession had the courage to stand and fight for its maintenance. In my opinion, this quest is the highest attainable in human life.

There were doctors learned in the law and perhaps in medicine, who talked with Christ in the Temple in his twelfth year. They have never been afraid to try to find out. They have fought ignorance and knavery since the days of amulets, charms and witchcraft, and from the dens of iniquity and quackery they have rescued by honesty and courage, millions of bodies and souls blinded by fear and superstition.

They have not been afraid to take up arms in war for truth, honor, or the glory of a righteous cause; and, more than that, they have by thousands and thousands stood unarmed in the field hospitals when their country was engaged in battle, giving up their lives to shrieking shells and other engines of death in a noble effort to allay suffering and save the lives of stricken humanity.

They have not feared to leave homes, wives and children to go into those stricken coun-

tries where grim pestilence hung like a black pall, and where the air was charged with the poison of death, to minister with loving hands and smiling faces to those upon whom this grim monster had laid its chilling touch.

They have not feared to take desperate chances in remote spots, removed from advantage and aid, and with the courage of Spartans, stake their lives and reputations upon single judgment in an honest effort to relieve mankind.

It has been a broad and generous profession. Doctors have for all times submitted in kindliness to the impositions on them by their patients as the general advisor in families, in serious matters outside of their profession, without remuneration or reward, bringing by their intelligent advice and aid much success and prosperity to trusting and admiring patients. This has broadened him, made him kind and tolerant. It has taught him to bear the burden of diversified responsibility and given him a veritable storehouse of general information.

It has been necessary for him to learn that it is a life of sacrifice, for in the necessity of doing for others, he has learned that he has little time to do for himself.

Like all great professions, the medical profession has been the target of much criticism which is modified and tempered in just re-creation by the fact that all who have criticized him come finally to appeal to his judgment and honor in the hour of greatest need, and also by the evidence of our hearts which refute this distrust when we confide to him not only our lives, but more importantly the lives and welfare of our beloved ones.

He is the recipient of our closest confidences. We lay bare to him the secrets of our poor bodies, and the sordid story of our abuses of nature and her great and good gifts to us; and while we can remember that there was a traitor among the Apostles, and that the most brilliant and attractive soldier of Washington's day made of his name by treachery an epithet of shame, yet we cannot recall to mind a great doctor who has stained his name or that of his profession, by betraying a secret sorrow or misfortune confided to him by trusting patient.

He carries his secrets to that mausoleum to which he, like us, must finally come. He has ever been free and gracious with his talents and skill and it is of common knowledge that it is not necessary through his kindness that the poor and needy should suffer for medical aid.

It is a part of the ethics of this great profession that in time of need and emergency its skill is offered free to suffering mankind.

It is of record in thousands of notable instances that by his application and genius he

has discovered wonderful remedies and cures which he has refused to monopolize and has turned over without charge to the free use of the world.

He is mankind's friend from the cradle to the grave. He is the first confidant and friend of the young mother in the initial mysterious pain and woe which racks her body and disturbs and alarms her innocent mind. His is the hand and his the voice which encourages and sustains her through the awful stages of pain necessary to bring mankind to life. He is the first with tender hand and loving sympathy in assuring the breathing infant, and he deposits it as a living charge with her who has risked her life for it, and who in its birth by suffering has joined, through agony, the angels whose very name is a touch of reverence, and whose attributes are tenderly inscribed in the hearts of every honest man in the sweetest of English words, "Mother."

He never turns back when he has enlisted for the sick. He faces poverty, infection, vice, with the same intrepid spirit because in the great faith of his heart he believes the curing of men is a charge from God.

He rides when the world sleeps, and he must go when weary or sick, but he must go, with a brave heart and smiling face because there is no sulking tent for the doctor. He must stand the test of courage; he must close the eyes of the dead and go on and on to the bedside of the living, leaving with the dead the sting of defeat and the infection of sorrow, for the living must have no hint of this. The garb of mourning must not be carried into the sick room. It must be quickly changed at whatever cost, for the patient's good, to that of hope and cheer.

His private interests must be foregone for it is the law of his profession that the call of humanity is supreme, and he must lay aside pleasure, joy and rest to answer the imperative call of the duty which he has assumed when he entered the ranks of this great profession. He has trying times in foregoing what he likes, because it is assumed in his undertaking to get these things for others that he waives them for himself and his interests.

In his life he must face the fact that he is credited with success as his duty only, and condemned without stint for failing. He must have sympathy for all, and patience with his sick, because the patient demands the one and success requires the other. He must tell the truth, and the great doctor would as soon desecrate the Cross as to deceive a trusting patient with a lie.

His kindness gained from habit and patience makes him the beloved of the children in the household, and the mainstay of the

mother whose anxious heart is searching for news or relief for her suffering sick.

He administers to the body and the mind. He treats the millionaire and the pauper, and he does his best for both. He must restrain his private sympathy in the agonizing scenes which come before him, of family suffering, because he needs an iron nerve in the pursuit of his work.

He puts humanity above compensation, and his firm voice is listened to with respect even in indigent institutions where reason is overthrown and mentality shattered. When the prosperous and even the poor have earned their rest by a day of toil, if you could look down from a high eminence into the darkness, you could see his vehicles as they flash through the night to bring hope through darkness, wind, rain, and snow to some poor sufferer whose fevered groans are changed to sighs of relief at his coming.

Away with scoffers at this work!

Away with cruel jests and slander!

It is the mother endowed by God who trusts him over her most precious possession, her child in illness and pain.

It is the child whom God has given the prescience to judge of truth that lifts up its little hands to him and smiles from a bed of anguish.

If his benefactions to man could be collected and erected as a tower to his life and work, it would put to shame the Tower of Babel, and make mere playhouses of the tallest of modern structures.

And in this contemplation, and with this view, I rejoice that we have one among us to-night who is a worthy subject of this life picture, and who has done and is doing all of this to such an extent that his great brothers in the Nation have seen fit to crown him with an imperishable crown of their admiration and esteem.

Dangers from Camphor.—Happich injected camphor into rabbits and guinea-pigs and the results confirmed those reported in the literature in regard to the great difference in the effects of camphor when it is inhaled or injected into an artery or vein. He ascribes the difference to the neutralizing of the injurious influences of the camphor by glycuronic acid which is generated fresh in the pulmonary circulation by the combination of oxygen and sugar. When the camphor is to be injected into a vein or artery, the individual condition in regard to the presence of adequate amounts of oxygen and of sugar must be estimated. When either of these is known to be abnormally diminished, then the use of camphor should be restricted. This applies especially, he says, to patients in inanition, the insane, cancer patients, typhoid convalescents.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

REFORM IN MEDICINES.

The proposed Royal Commission on Quackery. There seems to be little doubt that the propaganda against "patent medicines" in Great Britain has reached the place where a royal commission will be appointed to investigate the nostrum evil. While the recommendation for the appointment of such a commission has been fathered by the British medical profession it is probable that if the investigation is broad and impartial, the medical profession of Great Britain will not be held entirely blameless for the very evil it deploras. This for the reason that, although willing to condemn the use of secret medicines by the public, it has not kept its own skirts clean as is shown by the free scope which nostrum advertising enjoys in first class British medical journals. The British medical profession will find difficulty in justifying its position on the nostrum question. Its past attitude will do much to offset the good that such a royal commission might otherwise accomplish.—(Jour. A. M. A., Feb. 3, 1912, p. 349).

Duffy's Malt Whiskey advertisement. Certain newspapers are carrying advertisements which claim "Duffy's Pure Malt Whiskey Cures Consumption," "The greatest known heart tonic," "It stimulates the blood," "Cures asthma."

What do you think of newspapers that will sell advertising space to such a fraud as the Duffy Malt Whiskey concern? What do you think of medical journals that will carry advertisements for the same fraud? The following carry Duffy's Malt Whiskey advertisements: Buffalo Medical Journal, Massachusetts Medical Journal, Medical Standard, Medical Summary and Medical Brief. Most of these are mere advertising sheets, the Buffalo Medical Journal being a notable exception, which exist because phy-

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

sicians patronize them. As to the public one medical journal looks much like any other medical journal, the profession finds it difficult to persuade law-makers that its fight against nostrums is in the public interest.—(Jour. A. M. A., Feb. 3, 1912, p. 350).

Honors are Even. Among those who shared in the honors distributed on the occasion of the Dunbar ceremony were two British "patent medicine" exploiters, who have made their millions from the gullible sick, and who have now received the order of knighthood from King George. This reminds one of that genial personage whose relationship to the Duffy's Malt Whiskey outfit and the canning company that sold short-weight products has often been the subject of comment and whom a free people elected to the vice-presidency of the United States.—(Jour. A. M. A., Feb. 3, 1912, p. 351).

Oleum Telesphoros. Albert P. Mathews, Ph. D., professor of physiologic chemistry in the University of Chicago, dissects the much overworked scheme on the part of manufacturers of proprietary remedies of investing very ordinary substances with most extraordinary properties—and names. He points out that this proprietary, which is recommended for use in abdominal surgery for the purpose of preventing adhesions, appears to be "oleo oil" or "oleomargarine". Sarcastically he suggests: "The statement that, being derived from the omentum and appendices epiploicae, it is hence 'no more than natural that one of its greatest spheres of usefulness should develop in its application to abdominal surgery,' will carry great weight with those who believe that kidney beans are panacea for kidney disease and that lunacy is due to the moon."—(Jour. A. M. A., Feb. 3, 1912, p. 363).

Industrial Inhalation of Flour Dust.—Ferranini found that the dust inhaled was apparently digested and absorbed and thus did no harm as a rule. But when the dust was in excessive amounts or the air passages were diseased, the dust accumulated unmodified in the bronchi and alveoles. His research was carried on in the rooms where the flour was put up in bags, and the vital capacity of some of the workers there was found much reduced from this obstruction of parts of the lower air passages, when the natural conditions of digestion of the inhaled dust are suspended.

Bladder Papilloma with Ureter Calculus for Nucleus.—After removal of part of the papilloma at three sittings, the patient passed an oxalate stone and all the pains which had tormented her for three years ceased at once. The unsuspected stone had been impacted in the ureter mouth and the irrigation from it had induced the papillomatous growth over it.

OFFICIAL ANNOUNCEMENTS

DRUGGISTS' NARCOTIC LAW.

Frankfort, July 11, 1912.

To the Editor:

I am enclosing you a copy of the Narcotic Law. The Board of Pharmacy circularized the druggists of the State on the subject, and while there are still some who seek to evade the requirements of the law as a whole the druggists are making a determined stand for its enforcement. We are sure that the entire best elements of both professions will solidly uphold the statute.

The trouble has been—or one trouble is—as our inspector has found, that some druggists will supply themselves with whole books of ready-written prescriptions for Morphine. It will be the policy of this Board to prosecute any druggist indulging in this practice after he has been warned that it is regarded simply as an evasion of the law.

Yours truly,
J. W. GAYLE.

AN ACT TO REGULATE THE SALE OF OPIUM OR ITS ALKALOIDAL SALTS OR THEIR DERIVATIVES, OR ANY ADMIXTURE THEREOF.

Be it enacted by the General Assembly of the Commonwealth of Kentucky:

Section One. Opium or its alkaloidal salts or their derivatives, or any admixture containing opium or its alkaloidal salts or their derivatives, shall be sold or dispensed only by a registered pharmacist upon the original written, dated and signed prescription of a legally licensed physician or dentist or veterinary surgeon; and only one sale shall be made on said prescription, and each such prescription shall state upon its face the quantity of said opium, its alkaloidal salts and their derivatives, also the name of the patient and the date said prescription is filed. And opium or its alkaloidal salts or their derivatives, or any admixture containing opium or its alkaloidal salts or their derivatives, shall be sold at wholesale only to registered pharmacists, legally qualified physicians, dentists, and veterinary surgeons. Provided, however, that any preparation, patent, proprietary or otherwise containing not more than two grains of opium or one-fourth of a grain of its alkaloidal salts or their derivatives to the ounce, or admixture of ipecac and opium commonly known as Dover's Powder, or the anti-spasmodic mixtures of the National Formulary official at the time of sale, or lotions, liniments, suppositories, ointments, and plasters, plainly labeled "For External Use Only," may be sold or dispensed by registered pharmacists without any prescription.

Any registered pharmacist, legally licensed physician, dentist, or veterinary surgeon, or any person not a registered pharmacist; who shall prescribe for, procure, or sell, or dispense to any person opium or its alkaloidal salts or their derivatives, or any admixture containing opium or its alkaloidal salts or their derivatives, or otherwise deal in the same for any purpose other than for the legitimate use as herein provided, shall thereby render himself amenable to the penalties as in this act provided. And provided further that the provisions of this section shall not apply to the sales made by wholesale druggists to each other or to registered pharmacists or to legally licensed physicians, dentists or veterinary surgeons, or to hospitals, sanatoriums, colleges, public, and scientific institutions, nor to sales made to manufacturers of proprietary or pharmaceutical preparations for use in the manufacture of such preparations, nor to the sale at wholesale to general merchants or at retail by general merchants of patent or proprietary medicines containing not more than two grains of opium or one-fourth grain of morphine, or one-fourth grain heroin or three-fourths grain of codeine in one ounce. Any person failing to comply with the requirements of this section shall be deemed guilty of a misdemeanor and upon conviction shall pay a fine of not less than twenty nor more than one hundred dollars.

Section Three. All acts and parts of acts in conflict with this act are hereby repealed.

(Signed) CLAUDE B. TERRILL,

Speaker of the House of Representatives.

EDWARD J. McDERMOTT,

President of the Senate.

Approved March, 14th, 1912.

(Signed) JAMES B. McCREARY,

Governor.

House Bill Number 203 Originated in the House of Representatives.

Attest: JAMES E. STONE,

Chief Clerk, H. R.

RESOLUTION UNANIMOUSLY ADOPTED AT THE 35TH ANNUAL MEETING OF THE KENTUCKY PHARMACEUTICAL ASSOCIATION.

WHEREAS the medical and pharmaceutical professions are two distinct and separate callings, each being dependent upon the other for its highest and ultimate success—the duty of the physicians being to diagnose and prescribe, while that of the pharmacist is to compound and dispense; and

WHEREAS, the recently enacted narcotic law prohibits the sale of opium, its alkaloidal

salts or their derivatives, and preparations containing them, except upon the original written prescription of a legally qualified physician, said act specifically providing that:

“Any registered pharmacist, legally licensed physician, dentist, or veterinary surgeon, or any person not a registered pharmacist, licensed physician, dentist, or veterinary surgeon, who shall prescribe for, procure for, sell or dispense to any person opium or its alkaloidal salts or their derivatives, or any mixture containing salts or their derivatives or any admixture containing opium or its alkaloidal salts or their derivatives, or otherwise deal in same for any purpose other than for the legitimate use as herein provided, shall render himself amenable to the penalties as in this act provided”; and

WHEREAS, the Kentucky Board of Pharmacy is advised that a number of physicians sell and furnish these habit-forming narcotics indiscriminately to the public, thus defeating and frustrating the very purpose and intent of the law, and

WHEREAS the Court of Appeals of Kentucky has decided that a physician “cannot sell drugs indiscriminately to persons calling for same, nor compound and sell them indiscriminately to all who may call for same,” and

WHEREAS the Kentucky Pharmaceutical Association has the greatest respect for and confidence in the Kentucky Board of Health in maintaining the ethics of its profession and otherwise supporting its high and beneficent ideals—said Board having endorsed and urged the passage of the Narcotic Law; therefore be it

RESOLVED, that the Kentucky Pharmaceutical Association, assembled in its 35th annual meeting petition the Kentucky State Board of Health to circularize every physician in the State of Kentucky that it is unethical, unprofessional and unlawful for any physician to sell opium, morphine, laudanum, heroin, codeine, or other habit-forming narcotics to the public.”

A copy; attest

J. W. GAYLE,

Secretary Kentucky Pharmaceutical Association.

Prophylaxis of Scarlet Fever.—Drigalski urges that the medical inspectors of schools should keep a special oversight of children recently recovered from scarlet fever. He found nephritis in thirty-five children who had apparently entirely recovered, among the 1,102 scarlet-fever children at Halle during the last four years. The nephritis was found almost invariably in children who had had no or very brief medical care.

ORIGINAL ARTICLES

THE BEST MEANS OF COMBATING INFANT MORTALITY.*

By ABRAHAM JACOBI, M. D., New York.

(PRESIDENT AMERICAN MEDICAL ASSOCIATION)

My principal duty and intense pleasure is to tender my thanks to the House of Delegates which selected me for the highest honor in the gift of the medical profession of America, and to my colleagues of all the fifty states who were good enough to approve of its choice. Nor am I under less obligation for their attendance on this occasion to such citizens, men and women, as by their presence here exhibit their interest in things medical and socio-political.

My everlasting gratitude is due for the mode in which this great honor was conferred on me. Being duly aware of the small measure of my merits, I was overjoyed to have reason to believe that I owed my election to my lack of efforts to secure it. My democratic training and the gentlemanly nature of thirty-five thousand members of the American Medical Association, like the principal citizens of all parties, resent electioneering importunities and abhor the humiliation and demoralization caused by gesticulating and shouting candidates for office and honor. I have the confidence that if there be in this or any other cultured assembly anybody looking for the highest office for the sake of power and preferment only, he will be deservedly disappointed. Whoever *sets out* to be the first, let him be the last. There is only one thing that is and must forever remain first—that is the medical profession of America, as represented in this American Medical Association, and its object, which in all its aims is only one and indivisible. That one and inseparable object is to promote the art and science of medicine, to unite into one compact organization the medical profession of the United States for the purpose of fostering the growth and the diffusion of medical knowledge, of promoting friendly intercourse among American physicians, of safeguarding the material interests of the medical profession, of elevating the standard of medical education, of securing the enactment and enforcement of just medical laws, of enlightening and directing public opinion in regard to the broad problems of hygiene, and of representing to the world the practical accomplishments of scientific medicine.

With all this, my professional friends are

conversant. I want to impress it, however, on our guests, lay friends both present and absent, for I want them to understand from the very wording of the constitution of the American Medical Association that their interests and ours are closely related.

In order to be powerful and influential, you must not only be wise but numerous. In last year's official report you were told that it was not prudent to increase our number. In fact, you are 35,000, and the largest medical association of the world. But please remember that yours is also the largest country of the world. There are 100,000 medical men besides us, with the same rights to enter and the same duties to perform. We have been told that reasons of finance are among those which should restrict our number. I appeal to you and to those 100,000 outside. A big bank account appeals to our treasury, but glittering gold never saved a country nor a soul. If you have money, it is yours to spend as you have made it. See to it that your House of Delegates spends it in increasing, and consolidating, and strengthening your Association. Our colleagues in the vast country want to be invited; then they will come in. They must learn what we are, and where their interests are—and the interests of the public—from better sources than the hordes of irregular manufacturers and the "freedomers" whose bitter attacks convey what knowledge many millions are permitted to have of the American Medical Association. Let the people understand the meaning of the American Medical Association and its doctors through our doings, and not through the scurrilous lies of our and the people's enemies. My hope is for an annual increase of thousands of members. Multiply and be fertile. Stand still awhile, and you invite decline.

It is by vast numbers only that our profession will ever attain its legitimate influence in politics and in society, and such beneficent power as Socrates, Descartes, Kant and Gladstone claimed for it. The proclamation of a great principle may impress many philosophic minds, but its realization demands the labor of the enlightened democratic masses. That is why from this exalted position of mine I beg to contribute a share to the discussion of a subject which has enjoyed an important place in the best brains and the warmest hearts of our enlightened and philanthropic era. I allude to the great mortality of the infant, and the numerous efforts to combat it. You are acquainted with them all. Many fair results have been accomplished; to add to them, is my ambition. For infants must not be born merely to be sick, or to die.

The Committee for the Reduction of Infant Mortality of the New York Milk Committee

*President's address before the American Medical Association, at the Sixty-Third Annual Session, at Atlantic City, June, 1912.

has made an arrangement with the Russell Sage Foundation which will furnish a nurse who will look after a thousand pregnant women, with a view to enable them to bear infants with *improved resistance*. The mother will be provided for in case she is overworked. Which one of the poor is not overworked?

According to the Milk Committee, and other authorities, 17 per cent. of infant deaths are caused by congenital troubles. One-third of all of them occur before the first month has passed. The great remedies are recommended. One is that no midwife be allowed to handle any of these cases; the other is that after confinement rest be provided for the mothers, and that the children be referred to milk stations. There is no worthier organization than that committee. What it sets out to do, it performs. It cannot help being restricted to charity so long as one-half of us is condemned to ask and take it, and the other obliged to give and teach. The latter is probably the most valuable performance of the committee. As its activities, like those of its kind all over the country, are meant to be thoroughly altruistic, it is entitled both to praise and to criticism. I hope it will appreciate the former and make use of the latter.

Look at that program: first, no midwife for any of the thousand mothers. You ask, "but who?" Second, the Milk Station for the child because the charitable people want rest provided for the mothers, *at the expense of the baby*. If that be a good program for one thousand women and one thousand babies, if that be the best that can be invented or discovered for the one thousand lucky enough to fall into the hands of charity, what is to be done with, or for, or against those millions beyond the reach of the Sage Foundation? But you suggest, these one thousand mothers and babies are to serve as object-lessons only, to be imitated by the millions. The least, then, we must hope and work for, is that the millions of women to be confined and the millions of babies to be born now and in the future, should participate in the same benefaction which is promised a few. The universal object is to save and raise babies. My program is different, inasmuch as it suggests addition and changes.

If 17 per cent. of infant deaths are caused by congenital troubles, study these congenital troubles and obviate them. The baby's life and pathology begin nine months before its birth.

If one-third occur in the first month, study and combat that first month, and the indications arriving during and after labor.

Your dealings are not with children but with infants; not with infants only but with the new-born that is just terminating its em-

bryonal and fetal evolution and expects to be treated like a new-born human animal and not like a calf.

No midwife is to handle the case; indeed no midwife *will* handle any of your cases for you have none, with rare exceptions. It is proper attendance, however, which society owes to the woman and the newly-born, as a duty to them and to itself. They are valuable assets, both of them. Unless *that* be granted, no discussion is competent.

In one of the programs to relieve the coming child and the struggling mother, I read the demands of absolute rest for at least four weeks before and six to eight weeks after confinement; nursing and feeding, both gratuitous when required; and hospitals for the illegitimate and—when needed—the legitimate confinements.

By the Milk Committee, satisfactory *rest* is wanted for the mother. That means that she did not have it in time, before or after, the baby came. If rest means a long rest in bed, and milk station and no breast-feeding, you deprive her of her most important woman's privilege and office in life after child-bearing, and of the facility of getting well radically and physiologically. For without nursing the breast is liable to become atrophic and the uterus subinvolved. And the infant? Well, the infant, to give "rest" to the mother, is deposited on the altar of a milk station.

I shall be as brief as possible, for I do not believe that the speaker should have all the fun at the expense of his audience. On the other hand, I want to say my own things in my own way—perhaps taught by Jonathan Swift, who preferred to express his opinions "for the amelioration of his hearers, more than for their entertainment."

What the *world* wants is healthy babies. What the *baby* wants is full health and weight; that means a competent mother, sufficiently fed to have a quiet night, free from excessive labor through the day, exempt from a local curable disease that may interfere with the development of the child within her or undermine her well-being, her nursing qualities, and future pelvic and general health. What the *mother* wants is what she has a right to expect, as a reward for the service she renders to mankind in the shape of a healthy baby: a place as healthy as the best hospital without disrupting the family. Modern society is built up on the family, the crude teachings of anarchial and a few early socialistic doctrines notwithstanding. No woman will consent to being taken to a hospital unless desperate need compels her to go. To tell a woman she may die unless she go is a cruel sentence. Society is beginning to appreciate that it owes human beings a human dwelling-place, with air enough to breathe in.

If you build houses unfit to breathe in, you steal air which is common property. What *society* wants is men and women citizens. But in order to be able to rely on their cooperative functions, it must see to it that in its book of ethics the term of charity is supplanted by responsibility. It is useless to call that socialism or communism. It is the substratum of every religion and every humanistic philosophy. I like to avoid the term socialism and its alleged dangers, but only by abolishing the social causes engendering them.

Poets have told mankind that once, in the best olden times, the world was a garden, and they want it to become so again: statesmen—not politicians—have exerted themselves to disseminate prosperity and affluence; great physicians have looked for means to ward off disease and prolong an enjoyable life; jurists have endeavored to make the globe habitable by locking up or killing criminals, or the hopeless and dangerous insane. They all deal with those who are alive and, justly or wrongly, in possession of the surface of the earth. We are expected to deal with the present only, and to fight the evils which seem to be uncontrollable now and in the near future. Is there no way to prevent those who are born into this world from becoming sickly both physically and mentally? It seems almost impossible as long as the riches provided by this world are accessible to a part of the living only. The resources for prevention or cure are inaccessible to many—sometimes even to a majority. That is why it has become an indispensable suggestion that only a certain number of babies should be born into the world. As long as not infrequently even the well-to-do limit the number of their offspring, the advice to the poor—or those to whom the raising of a large family is worse than merely difficult—to limit the number of children, even the healthy ones, is perhaps more than merely exensible.

I often learn that an American family has had ten children, but only three or four survived. Before the dead ones succumbed they were a source of expense, poverty and morbidity to the few survivors. For the interest of the latter and the health of the community at large, they had better not have been born.

Theoretically and practically the addition of unhealthy, sickly, sick and contagious children is a misfortune to the newcomer, to his parents, and to society. Therefore a clean bill of health should precede matrimony. The clergymen who refuse to marry couples without it are good citizens, and the health departments are bound to see to it that contagious diseases, mainly sexual diseases, should be reported, watched, and cured. Nor is this all: Hereditary influences propagate epilepsy, idiocy, cretinism. Such persons

must not be permitted to propagate their ailments.

Now we build asylums for the diseased, neuropathies, and drunkards; nurseries and schools for epileptics,cretins, and idiots; sanatoriums for incipient tuberculosis, and refuges—still too few—for the dying consumptives, withal conscious of the fact that our only hope of finally exterminating tuberculosis lies in the perfect but comfortable isolation of hopelessly advanced cases. Surely we try to cure and prevent. Do we not begin at the wrong end? Consumptives, and epileptics, and semi-idiots are permitted to propagate their own curse, both what is called legitimately and illegitimately. Human society should have pity on itself and its future. The propagation of its degenerates, and imbecile, and criminal should be prevented. We have no positive laws yet for the syphilitic and gonorrheic who ruin a woman's life, deteriorate her offspring—if she have any—and impair the human race. We have come to this: that half of us are obliged to watch and nurse, and support the other half, many of whom should never have been born. In morals and in money, the degenerate are an expensive detriment. The only protection for the nation, for mankind, is to assure a healthy, uncontaminated progeny. Strict laws are required to accomplish that: such laws as will be hated by the epileptic, the consumptive, the syphilitic, and the vicious. No law ever suited the degenerates against whom it was passed, and it is unfortunate that while disease and incompetency and vice are to a high degree hereditary and contagious, moral health and virtue are not so to the same degree. Now those for whom the responsibility of the state does not exist are exactly those who are most entitled to it—the newly born.

Altogether, babies have a strenuous time of it, not only after birth. Heredity, degeneracy or incompetency is often caused by social influences. Financial temptations or necessity make women select not the strong and healthy men, but the old and rich. Their children are having less and less vigorous offspring. Rich and profligate boys spend their sexual powers on prostitutes and save little for possible babies. The lack of children in American families is not always due to voluntary abstinence. Thus the future of the American population has to rely on the offspring of the immigrants, and the American type of the next century will not be much influenced by those whose ancestors came on the Mayflower. Modern industry reduces the vigor and vitality of men, and woman and child labor exhausts the mothers and fathers of the future and present generations. Millions of men are prevented from contracting a marriage by pecuniary want and the im-

possibility of satisfying their sexual hunger except with prostitutes. That is true not only with regard to factory hands, clerks, and employees generally, but to the picked men of the people. Army and navy, the millions of soldiers and marines of all the nations of the globe, whom we are told by our self-styled leaders to imitate, withdraw the vigorous men from natural modes of living and labor and propagation, and prevent them from marrying in time; and wars, the cynosures of our coarse politicians who take the place that should be filled by statesmen, kill and cripple and deteriorate the best muscle of the land and tempt them into perdition. Only the "weaklings" are left—and their offspring! It is sad to contemplate the short-sightedness of our loudmouthed leaders and their heelers.

The history of the newly born is pictured on their bodies. Pinard weighed numerous new-born babies. Those born in poverty were 10 per cent. less in weight than the others. Many were premature, their mothers injured and sick afterward, and without milk. Of that class, from three to four times as many die when at home as when in a well-regulated and well-fed hospital. Their subinvolved uteri and parametritis are very common occurrences and are the sources of lifelong invalidism and treatment. Those few are fortunate who need not complain like the woman healed by Jesus, who had suffered all her life from her illness and from the physicians. Those are not so fortunate who are treated according to the last magazines' academic discussions demanding an early day for getting up. A woman of the million, permitted or ordered out of bed to work, is the pivot of her household or her small farm or shop, or the live part of her lifeless factory machine. She is not like one of your first class paying hospital appendicitis patients who may be ordered out of bed for a half hour or a few hours daily, and will not be harmed thereby. She will continue to convalesce when she returns home. But the woman of the middle class or the poor who is told or permitted to rise early from an appendiceal wound, a uterine wound, or after confinement will add to her endometritis, her phlegmon, and her adhesions. All that is why even apparently simple questions of medicine will never be answered without the consideration of social questions, and medicine must more and more become the guide in the solving of social problems.

A decided physical inferiority at birth is a common occurrence. Ballantyne experienced in the Fulham Infirmary as high a percentage as 21.9. They are called unfit, when born of overworked, underfed, and neglected women. Their number is much smaller and very trifling when their mothers, when poor, are looked after long before the uterine life is term-

inated or when circumstances, financial or sanitary, are more favorable.

Many premature, feeble, thin babies of unpromising weight may be saved when there is ample care, such as a midwife will more readily give than a doctor. If that be absent, the baby's life is endangered. Is salvation worth while? Who can tell, unless you try? Kant, Goethe, Hehnholz were puny waifs, whose lives were despaired of. But they have furnished elements of culture to the world of which we might have been deprived if they had been without the midwife's care and close attention. Luetens is said to have been 5 1-2 inches long. He died when 80 years old. He wrote eighty books, not many of them poor. That is an achievement, though not always pardonable, or even laudable. There are more men 80 years old, but they are not all guilty of writing eighty books.

Hard labor up to confinement interferes with the life or the health of the fetus and the new-born. The least that can be done for the mother is a reduction of working hours pregnancy, and protracted rest after confinement. The woman's worst occupation is that with metals, mainly lead. Their percentage of premature births and miscarriages was 53.6; while those with other work furnished another sufficiently formidable number, viz., 17.2. Lead, mercury, phosphorus, copper, iodine, aniline, and nicotine have been found in the amniotic liquor and in the fetal organism.¹ The indication is clear; less work, less hours, no directly unsanitary occupation, several months' absolute rest after confinement. The living result will be harder and heavier, and more resistant babies.²

When the baby is born, it wants many things; among others air and food, mostly food. Maternal milk is the only safe nutrient for the little stranger. Its quality is not much influenced by emotions, cares, worries; occasionally, only, by medicines taken by the mother, or rarely by her average food. Its quality is only temporarily altered by menstruation, and never causes a change that justifies the interposition of artificial feeding. The daily quantity is rarely less than a quart. Maternal affection, the wish to nurse, the act of suckling increases the quantity. There is no such thing as absolute absence of milk secretion. Essential alterations in the articles consumed by the nursing woman are not demanded. As her appetite is mostly increased, she is entitled to so much more than her average consumption as is required by the one or two pounds needed by her baby. She may eat and drink what she digests and was used to; she may perform her duties, attend to her labors—even some factory work—and fill her time as her station in life suggests. There is no reason why she should not spend time in

shopping, concerts, theatres, lectures and parties, except the dog parties reminding you of 1790—even suffrage parades—provided she will not forget that she has a baby at home to welcome and feed. The checking of babies, with or without baby carriages, by department stores, is a convenient innovation, which improves the chances of babies, women and merchants alike. Elections are no longer so exciting, dangerous, or murderous as they were in our large cities as late as twenty or thirty years ago—so there is no objection to woman suffrage, whether it be considered a plaything, a civic duty, or a disease. Even so, there is no danger, for infectious diseases in the mother are no contra-indication to nursing, unless it be a small-pox case in an antivaccinationist; for not injurious bacteria but beneficial antibodies pass into the milk and improve the baby's power of resistance. All of these considerations prove the dangerous tendency of those of our colleagues who in their mistaken subservieney to the ignorant suggestions of fashionable and lazy ladyships fall in with their and the dairymen's teaching that cows are their proper God-sent substitutes. These accommodating friends of ours are, through shortsighted complacency, enemies of the race.

The mother's milk has certain protective properties not possessed by any artificial food or the milk of another animal. Experiments have proved that the latter may propagate the artificial immunity toward certain vegetable poisons—the ricin and abrin; and a wet-nurse may immunize her nursing by being herself immunized through diphtheria antitoxin. So the mother who ever was thoroughly infected with scarlatina or measles will, at least for the time she is nursing her baby, protect the latter against those infections.³ The infected milk of an animal will not have that effect; immunity is secured only by the milk of the same—that is, the human animal—which proves that we are superior to our animal brethren and sisters; unfortunately, only so long as we are young. Many of us when we lose our infancy lose our superiority.

The attentive doctor and the diligent midwife know that our women, poor and rich, suffer from no organic mammary degeneration. Large and small breasts can be educated into competent milkers. They can be roused into action after days and weeks of comparative inactivity, and into renewed efficiency after a recess of one or more weeks. It is quite well known, what I alluded to, that the very suckling of the baby is the best edu-

cator of the breast. That is why for the hundreds of thousands of mothers, the doctor should be the oracle; the midwife of the people, with her future education and her diligence, the trainer. Both should remember, or rather, learn, that a better milk-supply is guaranteed by not improperly and untimely straining the breasts' function. You do not milk a cow every two hours. A healthy newborn baby should never have the breast more than once every three hours; after the third month, he must get along with five meals in twenty-four hours, and he will turn out a baby worth having.

Milk contains substances organic chemistry never discovered or measured. They are the *ferments* which circulate in the blood. Some aid in the digestion of albumin; others, of fat and starch. Besides, there are defenders in it of the circulating blood; the *alexins* (Hans Buchner) destroy bacteria; agglutinins immobilize bacteria by bunching them; antitoxins formed in the infected vigorous animal destroy the poisonous toxins of the bacteria. When they are not sufficient for instance, in bad cases of diphtheria—we inject antitoxins formed in the blood-serum of another animal—for instance, of horses. Any mother that ever had a mild or bad case of diphtheria—or, for that matter, certain other infectious blood diseases—accumulates some antitoxins in her blood and tissues, and in her future milk, and thus protects both it and her nursing. It is possible that so long as the infant is at the breast it is for that very reason less liable to take diphtheria. The fact is that few babies of the first half year become diphtheritic. That is the period of nursing at its mother's breast—its mother's or another human female's, not, however, that of another animal. It is not chemistry alone, but also biology, which distinguishes the milk of their organic producers. Old Doctor Heim was told by a so-called "noble" mother: "I keep an ass for my baby. Ass's milk is as good for my baby as my own would be, is it not?" "Yes, yes," said the old man, "just as good for young asses."

In Berlin half of the babies were breast-fed in 1890; in 1900, only one-third of them. At the same time, another German town, Barmen, nursed four-fifths of its babies—during one year, 99 per cent. Of 575 straying and neglected women in a Berlin institution, 83.3 per cent. could nurse their infants; why? they were better fed than before, and gave up only when the Moloch of industry reclaimed them as victims. After these poor babies had enjoyed the privileges of some of the rich—viz., health and life—they were sacrificed again on the altar of anti-social circumstances. For during the first year of life, of 1,000 breast-fed babies seventy have died; of the artificial-

1. Bluhm: In Weyl's Manual of Hygiene, vol. viii.

2. Furth, Henriette: Die Mutterschafts-Versicherung, 1911.

3. Fifty years ago I could refer only to anatomic reasons which secured the very young against diphtheria.

ly fed, 270 up to 430. They have been counted by the statistician, by the parents and by the undertakers.

Wittingly or unwittingly, surely not meaning it as a grotesque joke, the Nestle Food Company has a picture on the cover of their circular. It represents a woman with immense wings—perhaps meaning an angel—flying off with two babies to unknown parts.

The mortality of babies below 1 year has been found—not estimated—to be, for the exclusively breast-fed, 6.98 per cent.; for those brought up on a mixture of breast-milk and artificial food, 9.87; for those fed artificially, 19.75. That means that somebody or something is to be held responsible for the deaths of thirteen babies who should live in good health and with good prospects. Babies turned over to milk stations, because their mothers are told to "rest" may easily belong to that class. It is true, not every baby can be nursed, but the exceptions are scarce. One was born of a mother who died of sepsis carried in part by a dirty midwife or by an infected or ignorant doctor. That is true, statistically, even now that other doctors boast of their asepsis. My own past life does not class me among those others. So I may plead guilty, and no one has a right to blame me for exaggerations. I am, or have been, in the same boat with some of you. Of the five hundred tracheotomies I performed before the Listerian era, of a thousand I assisted in, of thousands of scarlatina, measles, erysipelas during epidemics, and even hospital gangrene during war times—too many occurred while soap and water existed without being used at the proper time and in the proper places. We did not know better, but you do. Every case of death of sepsis in the mother should burn hell into the conscience of whoever permits it nowadays; every case of death from lack of breast-milk should cause a trial for homicide against a doctor or midwife, or mother. For the latter, it is true, there are, if not excuses, many explanations. Some mothers must get up after three days to do washing and scrubbing, and do it without a sufficient quantity of food—starving women make no milk—must make a scanty living in the factory, or in a small business; others go to afternoon teas and bridge parties, or have been taught by their fashionable doctors who agree with them in their suggestions that modern science has proved that a woman's udder may be replaced by a cow's bosom, that a milk laboratory's clerk will furnish printed schedules for the modification or alteration or substitution of food adapted for every month of an orderly Fifth Avenue infant.

But after all, truth will crop out. There is rarely a woman who cannot nurse her infant.

Ignorance can be learned from and taught by doctors, by midwives, by nurses, but ripe wisdom also. As half of our babies, in all countries, are born under the supervision of midwives, it is these who, when their education will no longer be so hopelessly neglected as in our country, in their more intimate contact with the people can exert the widest influence. They will best overcome the prejudice which derives from the well-lad people the notion that breast-feeding is no longer fashionable; they will prepare the nipples, teach cleanliness and antisepsis such as they have been taught in the schools of the—I hope—near future. Edith Peiper reports an increase within five years of from 55.7 to 72.5 per cent. of women who gave exclusively breast-milk to their babies in a public institution.

In a large midwifery school of Germany (Stuttgart), the percentage of women who nursed their babies increased from year to year under proper treatment and teaching. Of one hundred women, only 22 to 25 per cent. gave their babies breast-milk to the exclusion of other foods before 1884. Exclusive breast-milk feeding was furnished by 41.1 per cent. in 1884; 61.4 in 1887; 84.3 in 1888; 100, in 1902; 99.5 in 1903. All of these women were poor or in very moderate circumstances, but they were looked after and fed before confinement and after. It takes missionary work to accomplish results of that nature.

In our country, it is calves that are looked after by our government. The babies have no votes yet. They will wait.

I must give you a few more figures, though I may bore you. But I have more sympathy with the world's babies than even with you. I want every incredulous Thomas to leave this place convinced that every baby has not only the right to suck a mother, but also the facility.

Diétrichs reports the mortality statistics of 628 infants of the poorest married women of Cologne. Of 100 children born alive, three of those who were nursed for nine months or more, died before the end of their first year; of those nursed from three to nine months, twelve; less than three months, thirty-five, of those who were fed artificially, forty-seven. Forty-seven died out of 100 born alive, in one year.

Perhaps a report by Prinzing is equally convincing in connection with the mortality of other than intestinal diseases. During the years 1895 and 1896, the mortality of Berlin babies under one year, when breast-fed, was 7.09; when fed artificially, 38.6. Of 1,000 babies congenital debility killed 14 of the

breast-fed; 43.6 of those raised artificially. Of 1,000 babies:

	Breast-Fed.	Artificially-Fed.*
Gastro-enteritis killed.....	12.2	171.0
Atrophy and marasmus....	2.0	24.0
Convulsions	11.16	42.0
Bronchitis and pneumonia... 5.6		39.6
Pertussis and diphtheria... 8.3		19.3
Other diseases	17.2	46.4

*Alfred von Lindhelms, *saluti juvenutis*, 1908.

The illegitimate infants fared much better than the legitimate ones. That sounds paradoxical, but the former, when controlled by the authors, were obliged to nurse their babies; the latter were the babies of the mothers who returned to domestic and factory work, and were exposed to neglect and early and improper artificial feeding, mostly by strangers. Among living infants of the second year, the proportion is reversed, for obvious reasons. The lessons to be derived from these facts are intelligible. A social improvement of the mothers, but that only, will add to the chances of the infant population.

Boek found that of infants who died of intestinal diseases, 61.4 per cent. were fed on flours; 24.3 per cent. on cow's milk; 15.8 per cent. on a mixture of breast-milk and cow's milk, and 1.4 per cent. on breast milk.

During the siege of Paris (1870-71) the women were compelled to nurse their own babes, on account of the absence of cow's milk. Infant mortality under a year fell from 33 to 7 per cent. During the cotton crisis of 1860 there was a famine. Men and women starved, and on account of no money for artificial food, the women nursed their babies. One-half of their mortality disappeared. In the poor forest districts of the Westerwald the bottle-fed babies had a mortality of 20 per cent.; the breast-fed babies, one of 8 per cent.

In the *Berliner klinische Wochenschrift* (No. 28, 1911), Professor Franz publishes the report of the gynecologic divisions of the Charité. One hundred per cent. of his puerperal women nursed their babies. Dr. Kahn accomplished mostly the same results.

It is true that private practice does not reach the same number. Among the well-to-do, with better surroundings, better food, more rest, but greater indolence, less sense of responsibility, more money to throw away and more accommodating doctors to amuse them, and with more money with which to buy inferior food, the percentage of nursing women is smaller. Their daughters will know better, provided the doctors—we and our successors—will teach them.

G. Dufort reports on conditions prevalent in four districts of Belgium. Women objected to nursing, with a mortality of from 153 to 252 per one thousand, in the first year. Then

the government and a private organization took measures to improve the percentage of breast-feeding women. Not all governments mix up with such things. Some are not on the job, some are on the slump. This percentage increased in certain localities where it was lowest, within two years, from 4.3 per cent. to 17.02. That increase was due to the midwives who were taught by premiums, by the practitioners and by clergymen. You see doctors and priests are still good for something. In other districts the percentage of breast-feeding was 56.6 per cent. in 1907; in the first half of 1908, 57.1 per cent.; in the second half of 1909, it was 74.12 per cent. That means an increase obtained by the country midwives in two years of 17.6 per cent. More, there were midwives who could report 94.9 per cent. in the first half of 1908, and at the end of 1909, 100 per cent.

The same midwives made it their business to extend the duration of breast-feeding. In 1907, there were fifty-seven babies who did not receive the breast through the first half year exclusively; this number was reduced to forty-eight at the end of 1909. Of the infants who were kept at the breast exclusively through six months, 64.7 per cent. extended this time to nine months; 75.4 per cent. in 1909. The author again and again refers to the powerful influence the midwives—after having been instructed—exerted among the population—the women and the babies.⁴

In 1900, the German Empire lost 426,485 infants under a year old. That means 27.5 per cent. of those born alive. Of these, 61,340 are reported to have died of congenital debility. What is this debility? How did it occur? Something has caused it during embryonic and fetal life. A disease of the embryo or fetus. Infection through the placenta; starvation of the mother by poverty; overwork in a factory; poisoning by a chemical; prolonged labor; unattended labor; unskilled attendance, and some of the other causes I am going to mention.

Whatever among these influences can be avoided or cured saves infant life. It is our duty to look for the causes of debility and death in order to escape from them. We have spent more care on the health and efficiency of the cow and her milk than of the mother and her milk. No doubt the efforts to improve the chemistry and physics of cow's milk, and the beneficent activity of medical and lay milk commissions have borne fruit, and the safeguarding of milk by sterilization, pasteuriza-

4. Dr. A. Baletsky and Dr. M. d'Oelsnitz (Bericht, über den III. Internationalen Congress für Säuglingsfürsorge Berlin, Sept. 11-15, 1911, p. 789) express their satisfaction with the results of the Infant Protective Society of Nuremberg, which was founded twenty-five years previously, mainly for the encouragement of maternal breast-feeding.

tion and modification has saved lives, but we must look for a higher percentage of salvation. That can be reached, for even the average mortality of a single, mostly poor, country—Norway—has reached as low a standard as 8 per cent. under one year. Wherever financial circumstances are more favorable that should not be the lowest percentage.

What, after all, is a midwife, whose presence at or attendance on a confinement case must be shunned? An editorial of the *Boston Medical and Surgical Journal*,⁵ that cautious and elegant magazine, gives the following definition:

"The midwife may be defined as a person attempting to practice obstetrics without complete or even adequate medical education. The tolerance of such persons is an anomaly in an enlightened civilization. The midwife is a relic of medievalism, unhappily extant in the Old World, but whose persistence in our own community should not be encouraged by any form of recognition."

Meanwhile, Holland, Belgium, France, Italy, require a two years' course of schooling for their midwives; Norway, Sweden and Denmark, one year. Germany has had its midwifery schools for more than a century. Many countries subsidize their midwives, who live and practice in sparsely settled districts. Great Britain⁶ established in 1902 its Central Midwives Board, to supervise and control midwives for the specified purpose of preventing the death of women in childbirth, infant mortality, blindness, and physical degeneration.

There are in England and Wales 17,790 trained and untrained midwives—too many yet of the latter class. The British Empire's 108 midwifery schools—including four in the East Indies and one in Hong Kong—have not yet afforded sufficient facilities. But the *British Medical Journal* emphasizes the fact that even in the old type of midwives there is a great improvement in cleanliness and obedience to rules, one of which is the calling in of medical aid in cases with a purulent discharge.

And we? Fifty per cent. of all the births in the United States are attended by non-medical women—in New York, 42; Buffalo, 50; St. Louis, 75; Chicago, 86. The patients so attended are negroes, aliens, and natives born of aliens; that means one-half of our population; that means those who during the disappearance—voluntary, wanton or not—of the original stock and by additional immigration and multiplication will form what within two generations will be the type of the two hundred millions of Americans then living. And where are our midwives? Where are the 108 schools which little Great Britain deems—on account of their scant number—insuf-

ficient for her urgent needs? Where are the American safeguards of our fetuses and newborn? When our experienced and far-seeing president of Bellevue and Allied Hospitals established a small school of midwifery, he was applauded for his exceptional foresight and altruism. We think nowadays that the ocean is only a short bridge; but the experiences of Europe, established on a solid and constant foundation, do not travel on it. That is the way of indolence by which we negligently murder our forests, lay dry our river beds, cause our freshets, and kill or cripple our newly born. I wonder in which other country we could be expected to accept what I lately read, that people cannot receive obstetrical service under the midwife, "no matter how well trained for her vocation;"—I ask why not?—or agree with a well-meaning author who sympathetically cries out: "Professors are teaching midwives, so medical students are deprived of their professors' time;" or throw up our hands when Stokel tells us that it is "a curious fact that even among people of refinement the older and dirtier the midwife, the greater seemed the confidence placed in her ability and judgment." That is as sound, perhaps, as when the great English opsonin scientist publicly arraigns habitual bathing for its dangerous effect in admitting microbes through the clean skin—a desirable bedfellow he!—or when Knott⁷ tells us that "Lady Lawson, who died at the age of 116, never practiced ablation of any kind, or hardly in any degree, because, as she alleged, those persons who washed themselves were always taking cold or laying the foundation of some dreadful disorder," or the occasional preference given to an old doctor not though but because he is habitually intoxicated. There is still another line of mistaken altruism; Fenwick fears lest a midwife, scantily trained, compete with a physician. I should say, if she succeeds, it serves him right unless he owns a superior training. A pretty good doctor will not do for you or your wives or cases, any more than a pretty good egg for your breakfast.

Is there anybody here who remembers that when fifty years ago the question of the licensing of midwives was brought up before the Medical Society of the County of New York, it was voted down with all con except one? Ask our New York doctors at present. We know better now, and feel better about it. For we feel like citizens at present. We have also been told that all countries have found "the practice of midwives unsatisfactory." The fact is, however, that the other countries pretend to know their own business, and constantly add to the facilities and education of midwives as we do those of doctors. Some assert also that the attendant on a midwifery case

must either be a trained obstetrician or a subordinate "like our excellent trained obstetrical nurse." "The obstetricians are the final authority to set the standard. They alone can properly educate the medical profession, the legislators, and the public." Who educated *them*, if you please, if not the professional schools, and they themselves as best they could afterwards? The midwives are not even mentioned as worthy to be educated. Do our obstetricians demand all the obstetric practice? I am prepared to bid a hearty welcome to the evening-dress obstetrician—who charges \$200 or \$300 or \$500 a job—to the confinement where the man earns ten or fifteen dollars a week, or the woman thirty-seven cents a dozen, and the children nothing.

In spite of English complaints concerning the insufficiency of midwifery attendance, the reports are very promising. In 1910 there were 321 midwives in Liverpool, 198 in Birmingham, 159 in Manchester. In Liverpool, the average number of cases per midwife was seventy—one had 500 cases. Of all the births attended to there were by midwives in Liverpool, 71.9 per cent.; in Birmingham, 63.2 per cent.; in Manchester, 57.2 per cent. Stillbirths attended by midwives were 391 in Liverpool, 212 in Birmingham, 279 in Manchester. Their honest discipline is exhibited in the following figures: Medical assistance was called by 1,015 midwives in Liverpool, by 774 in Birmingham, and 2,279 in Manchester. The indications for such calls, under the universal rules, are high temperature, abortion, laceration, illness of the patient, imperfect removal of the placenta, puffiness, convulsions, large varicose veins, sores on genitalia, malposition, trauma, hemorrhage, venereal diseases.

This very day the system under which they work with us is an absolute lack of system, slovenly and shiftless—no instruction is offered, no examination demanded, no supervision enforced, and the babies swell the universal mortality.

What is it that a midwife should be taught? Common sense and the experience of other countries should tell us, for we have none—I mean experience. We are only told that she is dirty, ignorant, untrained, superstitious, septic, the cause of invalidism, degeneracy and blindness. That is a list of statements exhibiting more temper than knowledge. For, indeed, in thirty-three of the fifty states and territories there is no law restraining the practice of midwifery or what is so called. In three there is no restriction whatsoever. In thirteen there is no provision for training, but there are, curiously enough, laws requiring examination and licensure. What is it, after

all, that every one of our states—indeed, after a while, the federal government—should demand on the part of a midwife who is to be the obstetric guide of fifty millions of Americans? In my opinion, she must have as moral a character as you expect in a male or female student of medicine or man generally—and, for that matter, of any American outside a penitentiary; a good common school education without Latin and Greek; a fair health so as to endure the hard work she means to undergo in future; a reputation for love of work and conscientiousness; and such knowledge of popular physiology and anatomy as the program of our future midwifery schools will designate. What they must surely teach, like the English schools, are four topics—the care of expectant women, the conduct of normal labor, the care of babies immediately after birth, the simple principles in an urgent case of artificial feeding—and the diagnosis of abnormalities, so as to advise the calling in of medical skill. As there are many, I shall spend a few minutes on the consideration of some of them.

The fact is, that of one hundred deaths under a year, 2.2 occur by injuries during birth, ten on the first day of life, twenty-five during the first two weeks, thirty-four during the first four weeks. Most of them should be saved through perfected knowledge and art, more skilful attendance than half our population enjoys, and greater acquaintance with the dangers of the newly born. You notice that a large number die from other than the usual causes, viz., indigestion.

A calamity never prevented by one of us, possibly by an attentive and painstaking nurse or midwife, is death by suffocation.

There were in England and Wales during ten years 10,009 *overlain* infants; in 1900, 1,774. In Liverpool, out of 960 inquests, there were 143 on babies that had died of suffocation from the same causes, by accident or malice; in London in 1900; 615; in 1901, 511; in 1902, 588. In London, they had annually 8,000 official inquests, one out of fourteen of which were on overlain infants. A serious complication of labor in asphyxia. It may be caused by the mother or by the fetus. Disorders of placental circulation, mostly toward the end of labor, early loss of amniotic fluid, respiratory and cardiac disorders, disruption of the placenta, compression of the cord and cerebral pressure can mostly be prevented or moderated by appropriate aid. Asphyxiated babies may die, however, within an hour, or the first few days. Those who do not so die are apt to be worse off. They are very liable to become paralytic, idiotic or epileptic. Little shares that opinion, the contrary assertions of others notwithstanding, that a large percentage of cases of

spastic encephalitis ("Little's disease") is produced by congenital asphyxia. Hundreds of times, both in obstetric and in pediatric practice, have I, when looking for etiologic factors, received the uniform answer that the baby did not cry for some time after birth, and that the attendant had to work over it minutes, or even hours. Asphyxia must not be tolerated. A few moments' delay adds to the danger which may be averted by knowledge and skill. Losing a baby is a loss and bereavement; crippling it for life is worse. Accidents of the kind can be avoided by much less than the profound knowledge of medical experts, few of whom will ever deign to attend a mere case of common confinement. The statement on a certificate that the new-born is a still-birth means a statistical fact, not an explanation, still less an excuse.

Atelectasis is more apt to be relieved, and death from it more readily prevented, by a midwife than by one of us, no matter by what it is caused. Soft cartilages in the premature, feeble muscles, defective nerve centers and lungs, but mainly hepatization, early pleural effusion, straua and compression of the brain are the usual causes. Frequent changes of position, warm and cold baths, shaking, forced inspiration, occasional closure of mouth and nose—so as to fill the medulla oblongata with an extra momentary dose of irritating carbon dioxide—an interrupted momentary Faraday stimulation and all the procedures demanded in asphyxia are advisable in atelectasis. A midwife should and can master all or most of these measures, as well as a doctor. The former is more efficient because she mostly uses more diligence and will spend more time than most of us.

The observing obstetrician or pediatricist or midwife has an opportunity to notice all sorts of microbic infections, such as tetanus, hemorrhages and the intense forms of syphilis. Its worst form is the pemphigus of the soles of the feet, which must be recognized within a few days. The midwife is the readiest to make the diagnosis, and to recognize the necessity of treatment. That does not mean her treatment, just as little as she will undertake the treatment of melena, sclerema, jaundice, sepsis, dermatoses, erysipelas, traumata or umbilical defects or diseases.

Some of the septic diseases of the newly born for the cure of which the doctor is always too late, or incompetent, are those which go by the name of Buhl, of Winekel, etc. They develop before any symptom is perceptible. The poisons which cause them are probably multiple and connected with the rapid metabolism occurring during, and immediately after labor. Many cases look like acute atrophy of the liver, or pernicious vomiting; or the main symptom is fatty degeneration, or hem-

orrhage, or intense jaundice. Overdoses of chloroform in predisposed women have been accused. Intense asphyxia I have seen coupled with, or causing it. There are many such cases which can be prevented by appropriate and instant aid, such as I plead for. Many, I believe, will be cured by vaccine therapy, provided it can be employed in time. That is possible only when the indication for it is suggested, or only suspected by a person who is on the spot and better taught than a common neighbor or nurse.

The mouth of the newly born is exposed to injury resulting from the antediluvian tendency of not leaving well enough alone. The habit of washing and rubbing the oral cavity of the newly born, even by clean fingers and rags, hurts the very thin mucous membrane covering the posterior part of the alveoli, and the punctated epithelial accumulations on both sides of the raphe. Doctors and nurses and midwives who do not know how to omit interference are dangerous. For the forcible removal of the epithelium leads to invasion of cocci and bacilli, and the mycelium of *thrush*. The latter, though easily cured by a strong solution of borax in glycerin, need not occur in the baby's mouth, for its habitat in the vagina of the mother is quite accessible, both in a private home and in obstetrical wards and in foundling institutions. A consecutive invasion of the stomach and intestines, of blood-vessels and lymph ducts, even of the kidneys and nerve-centers, may easily be avoided by a person who has been taught to prevent and to cure.

Constipation of the newly born should be recognized by the midwife. What I described nearly half a century ago as *congenital constipation* is the result of an excessive length of the sigmoid flexure. When its continuance for one or two days suggests it, enemata should empty the bowels. Unless that be done, moderate and later on serious costiveness is an accompaniment of the dilatation of the descending colon, and auto-intoxication. "Hirschsprung's disease" is rarely a fully developed congenital dilatation. If a midwife be too alert she is capable of preventing an operative interference. I was one of the alert midwives. None of my cases ever terminated on an operative table.

Ophthalmia is the source, not only of blindness, but of death through general septico-pyemia under the general symptoms of multiple abscess and arthritis. A series of cases I, like others, have observed, of vulvo-vaginitis, endometritis and peritonitis. That endometritis is always of long duration, may for anatomic reasons relapse indefinitely for many months and years, and often gives rise to contagious dissemination in families, in

hospital and asylum wards, by careless nurses and by gregarious bathing.

Uric acid infarction of the baby is a frequent occurrence of the second day until the end of the first week. It is rarely observed by the doctor (if any was employed) who sees the new mother perhaps once a day, if at all. Thus in this respect the well-to-do mother is worse off than the poor who is seen by a midwife whose visits are more frequent and more extended.

The tissues of the newly born contain more water than those of the adult; the difference amounts to 10 per cent. *Loss of water* is badly tolerated, while large quantities are eliminated at once through the lungs, kidneys and skin, and some through the intestines. Without a proper supply, the tissues deteriorate and the physiologic equilibrium is lost. That was always so—the newly born is conservative—and was considered normal. The baby had to be satisfied with reading in every text-book—even in the old ones from which some new ones are compiled—that he had to please the attending oracle by giving up 10 or 20 per cent. of his weight within a week or two. However, as the mother has but little milk during the first days, the least the baby has a right to expect is water—at least teleology ordains it so—the more so as the first mammary secretion means colostrum, which contains three or four times as much protein as the milk of later weeks—that means 3 or 4 per cent. That is mainly so—even still more so—when the baby is premature and endowed with less vitality than when born at full term. Neither you nor I shall undertake to change that, but the danger connected with it requires correction, and if artificial feeding be resorted to at all the food should be amply diluted. There is another reason for so doing. Uric acid sediments and renal stones are comparatively frequent in small infants. They are caused by the uric acid infarctions which, as a speedy result of the rapidly changing metabolism, are found in the diapers on and after the second day of life. Besides forming gravel and canculi, they give rise to occasional attacks of colic, to small hemorrhages and frequent cases of nephritis, with or mostly without, pyelitis. Neither I nor my pupils and friends have seen so many stones and inflammations since, for the last forty years, we made it our rule to feed the newly born on plenty of water. It is also demanded for the purpose of rendering the chemical and physical condition of cow's milk casein more digestible. As long as a human baby is not permitted to live on its mother, that fact is important to consider. Artificial feeding during the first days and weeks should furnish more than 75 or 85 per cent. of water, which is normal even for the adult.

Altogether, our infants and children are not supplied with water in sufficient quantity at any time. In our era of equality for all sexes and colors, we should recognize the rights of all ages.

When you are hungry you want to eat; when thirsty, you drink. The baby wants its equal rights. But no matter whether it is hungry or thirsty, it is condemned to receive the same food to quench both its hunger and its thirst. When it cries with hunger, it justly receives food from the bottle or breast; when it cries with thirst, it is given the same food from the same bottle—not mere water. I have often felt like presenting a bill to the legislature or to the professional philanthropist, enforcing, when father, mother and physician are thirsty, beefsteak and potatoes. I wonder how they would like that. A German pediatricist improves the method of giving water by giving the new-born tea and saccharin. What ten is, I do not know; what saccharin is, we do know. It is found to be a poison. That should, however, not have been the reason why our magnanimous Agriculture and Treasury Departments twice postponed the execution of the law which forbids its indiscriminate sale by the manufacturers of foods.

Midwives are more fortunate than we doctors. They need not know so much as a few taskmasters ask of them—for instance, two German professors, Salge and Siegert, who are so interested in the babies as to insist on midwives being examined on the intricate problems of metabolism. I fear, after having been a midwife sixty years ago and since, I could not pass to-day. Then, they need not know all the mixtures and mathematical formulas concocted by twenty of my pediatric friends, each one of whom is sure that the other nineteen are quite wrong. Nor need they be acquainted with the fifty artificial foods which were recommended by the *Deutsche medizinische Wochenschrift* a short time ago, and again rejected—all of them—in the very same year.

The teaching of midwives is not so difficult as part of our profession imagines it to be. We are defective ourselves, for there is a fact which seems to be agreed on by our college teachers, viz., that our young doctors are incompetent to conduct a normal or abnormal labor. As that is so, we, the practitioners, should try to learn some lessons by theory but more by practice. Their incompetence is the result of the insufficiency of our medical school instruction, which is acknowledged to have been scanty in spite of our four years' medical courses. The schools furnish neither systematic obstetricians nor competent general practitioners. I shall not be hard on them, however, for I was a teacher myself. That is

why the number of septic infections and of still-births is liable to be large in their practice. If that occur in the green tree—viz., among the men and women with medical diplomas—what can we expect from the untutored?

We speak against midwives and their detrimental doings, and their unreliability. Teach them their duties, which are not many; furnish beside instruction—which even for a hundred thousand physicians is scanty or none—so that they will learn the manual care of labor; let them be taught not to use medicines, not to operate, not to try even to remedy, as a rule, wrong fetal positions; teach them the use of soap and water, and antiseptics; enforce by law and custom the frequent change of their own clothing; forbid the simultaneous attendance on two or more cases; see that the midwife does not attend a labor case as long as in her family or immediate neighborhood there is a case of contagious disease, and she will cause or disseminate no puerperal sepsis. She must be examined and licensed and protected, like you and me.

Registration alone, however, will not do. Nor will our complaints do. Our responsibility does not cease when we decline it. Our duty does not end by sending and collecting a bill for an individual medical service. A death not prevented, a life not saved, is a blot on our escutcheon. The people want more. We are not yet—as the British government proposes—official state employees of the people. If there were not an excess of individualism among us, the attempt to force socialistic coercion on the profession of England would not have been made. Not yet.

Less than a year ago, the New York Academy of Medicine passed, among others, the following resolution:

"Whereas, some of the results of obstetrical malpractice are unnecessary, blindness, mental and physical degeneracy, and death of infants, and unnecessary suffering, invalidism, and death of mothers; and whereas both doctors and nurses in this country are given instruction in the treatment and care of child-bearing women and new-born infants, there is no existing provision for the adequate training of women who take into their keeping the lives and future well-being of this large number of both mothers and infants, be it resolved that the Section of Obstetrics and Gynecology of the New York Academy of Medicine recommends that measures be taken in this state to secure state legislation which shall provide for the training, registration, licensure, supervision, regulation, and control of women engaged in the practice of midwifery."

It is useless to attempt a comparison of a midwife with a medical man. They must be

considered individually. The ignorant doctor in obstetric work is the inferior of a well-informed midwife, and *vice versa*. I remember only two cases of sudden death caused by atmospheric air entering a large uterine vein—in both instances resulting from the nozzle of a fountain syringe introduced into the uterus before the air had all been expelled. In both cases it was a medical colleague that did it. That does not prove that we doctors do not know how to clean a uterus without pumping air into a vein—but I know of no midwife that could have done worse. Still, ignorance, like sinfulness, makes all mankind kin. The greater number of annual labor cases in the United States—more than a million—are attended by midwives. As long as these cases are uncomplicated, the presence of a bright trained woman should be, and is, welcome. She must have learned to distinguish the position of the fetus, and know when to call a doctor; how to do, in his absence, a version in cases of emergency; how to attend the eyes; hemorrhages depending on incomplete uterine contraction or from injuries—one of which is tearing off of the placenta—and how to recognize eclampsia, inversion of the uterus, the presence of a mechanical obstacle like fibroma or a contracted pelvis. She must know how to deal with asphyxia. More than anything, she must have been taught to appreciate two things: first, how to keep absolutely clean—that means to disinfect herself and her hands; second—and therein lies a secret of success—not to leave the woman. That is more than you or I do, or usually did.

The results of midwife practice do not always compare unfavorably with those of our professional brethren: Of 116 cases of ophthalmia neonatorum which were treated in the Massachusetts Eye and Ear Infirmary in one year, 114 were in infants attended by physicians, and two by midwives. Of thirty-three cases treated in the New York Eye and Ear Infirmary in one winter, twenty-two occurred in the practice of physicians, and eleven in that of midwives. Of the eleven midwives three had used nitrate of silver; of the twenty-two doctors, only one. According to these reports, if it were wise and proper to generalize, the doctors should be replaced by midwives.

In a period of years, 1905-10, the City of Manchester, England, has the following to say about puerperal fevers, and recoveries and deaths following them, in the practice of midwives and of doctors. In the practice of midwives there were 219 cases of puerperal fever, with forty-one deaths; in the practice of doctors, 275 with eighty deaths; in the cases attended by midwives and doctor, 100, with twenty-six deaths.

Nor are midwives' cases, those reported in 1910, inferior in results—forty-five puerperal fevers were treated at home, with a mortality of ten or 22.2 per cent; in Monsell Hospital, sixty-six cases with sixteen deaths, or 24.2 per cent.; in other institutions, twenty cases with five deaths, or 25 per cent.

The absence of skilled assistance from a confinement is one of the causes, not only of death, but of what is still worse, of degeneracy of the new-born. How many, nobody can tell. But it is worth while to reduce the number of 60,000 weak-minded or mental degenerates with which we are credited in the state of New York alone. The statement on a birth certificate that the new-born is a still-birth means a fact, not an explanation, still less an excuse. Many of them could be avoided if the women of the United States were protected against ignorance and indolence. When I was in active obstetric practice fifty years ago, I met in the tenement-house population many a case, which should have been saved if any bystander had known enough to afford manual assistance, such as that of a well-informed midwife. That, however, is only a part of the possible mishaps. What proper assistance may prevent is a vast number of paralytic, spastic, idiotic, semi-idiotic or epileptic conditions, mostly during infancy and childhood. How many? I do not know. But I have seen hundreds personally. Questions were as follows: How was that baby born? Did it take long? How long? Was it an instrumental case? Did the baby cry immediately? Was anybody present to help you? Did it take the doctor, who was called in, long, a minute, ten minutes, or one-half of an hour to make the baby cry? The answer gives the history of asphyxia, which—and that is my point—could have been prevented, or relieved, at once by a midwife. I hope there are many general practitioners here, such as I am or have been. They know how much they would have wished to be present on the spot, or to have a midwife to attend when they did not care to attend or could not do so. How many cases might have been carried to a safe end, when a little aid would have prevented intra-cranial hemorrhage caused either by direct lesion or thrombosis, can be surmised only when you remember the many patients with meningeal hemorrhage or inflammation who die within a week.

Now, my friends, you have been kind to me and patient, as hundreds of times before. That is why I shall now finish in a minute with a few conclusions for those who with me are convinced that healthy women and living vigorous infants are the best possession of this nation. They will not be conquered with treasures and cannon and corpses of

countless men; they need conservation only. What I want is that a pregnant woman should be in a condition to carry her fetus to its legitimate end in health and vigor, and be able to nurse her infant. Every text-book talks to us of the inability of women to do so, and indicates formulas and tradeships and factories from which to graduate toothless young Americans. One hundred per cent. of our women, however, can be made to nurse, even the "flower and fashion" of the land. From two to three times as many babies will live when breast-fed compared with the number of those whom they complacently try to raise on artificial foods. By breast-feeding you will save 100,000 babies that now die or become invalids, from no other cause but unnatural feeding.

Dangers which now attend the process of parturition for more than one-half of the women of this country must be modified, relieved or removed by the presence of a person instructed to conduct a normal labor and, when needed, to call timely aid. We want, for the benefit of the women who need midwives, 200 midwifery schools after English or German pattern. Let no legislature of any state pass without a bill or law to safeguard the newcomers and their mothers.

A town without an ample supply of good doctors and midwives and a village without one or two competent and responsible and licensed midwives, are like a tenement house without a fire-escape or a *Titanic* without life-boats.

19 East Forty-Seventh Street.

ANTI-TOXIN IN DIPHTHERIA AND MEMBRANOUS CROUP.*

By I. H. BROWNE, Winchester.

The wording of my subject is of my choosing, and I should have omitted the last clause; but had a purpose in the arrangement of the phraseology which will appear later on. My treatment of this subject shall be purely practical, leaving theory and disputations to book writers and scientists, while I tell briefly something of what I have seen and learned in actual practice of the "all controlling" power of diphtheritic antitoxin, in this scourge of the cradle and early life. But for motive we have in mind, in the wording of the title of my paper, I should think it a waste of time to say that antitoxine for diphtheria would be inert in membranous croup if there be such a thing as membranous croup, unless we concede in our nomenclature one's right to call laryngeal diphtheria, membranous croup, to which I very strongly object, as

*Read before the Kentucky Valley Medical Association, Torrent, June 25, 1912.

tending to confusion of diagnosis and consequent treatment. In the early days of antitoxine; observing the rapid disappearance of the visible false membrane, after a full dose of the antitoxine—fading away like magic—I was led to the false belief that this antitoxine would tend to the solution of the false membrane in the windpipe from every and any cause.

Now we are quite sure that this treatment would prove useless in laryngeal false membranous formation, except of this specific origin, if such false membrane ever comes from any other cause. In our first experience with antitoxine in the treatment of so-called "membranous croup" we were called to two cases in one family—two others had died in the same house within the week—and had the satisfaction of witnessing a rapid recovery. Within twelve months a scientist discovered the identity of the germ producing diphtheria and membranous croup, and the leaders in the world of science have abandoned the old name, and now call all such cases "laryngeal diphtheria."

In the very early days of diphtheria antitoxin its hardest battle for acceptance as the "panacea," which it has since been demonstrated to be, was in overcoming the widespread belief that the new remedy was producing Bright's disease, and if so, killing more than curing, for it is a truth of statistics that more children untreated die of Bright's disease than from laryngeal involvement, and perhaps almost none died in the old days of "inert" treatment except from one of these two accompaniments; and now all recover under full or proper doses of antitoxine used in reasonable time. The false idea that antitoxine produced Bright's disease so dominated the minds of our practitioners, the world over, that we dared not "press" in the cases of acute diphtheritic nephritis; being satisfied with using the ordinary dose, and surrendering our little patients to the inevitable.

This false theory dominated our practice for a number of years, till we encountered a case apparently hopeless, of laryngeal diphtheria, in which was administered to a nine months old babe, 6,000 unit doses at intervals of eight hours, till 18,000 units had been administered (in 16 hours) at the end of which time no improvement was noted, but some encouragement taken from a standstill, when the dose was doubled, giving 12,000 units at a dose, repeated at the end of eight hours; making 42,000 units administered in 32 hours. At the end of eight hours more the case was clearly under control, but the physician in charge, to make assurance doubly sure, administered 6,000 units more or 48,000 units to a nine months old babe in 40 hours. Clearly here was a life saved, but on securing a sam-

ple of urine, soon after, and subjecting it to the heat test, we beheld in horror a conversion of the urine into a solid mass, such as one would see from heating the white of an egg; and all hope was abandoned. But the heroic doses of antitoxin, administered for securing a solution of the membrane in the windpipe had done its work and the albumen was gone in 24 hours; the patient making a speedy and uneventful recovery. This lesson, burned into our brain, has given us a success that inspires us with a courage to believe that the recovery of every case of diphtheria, regardless of sequelae, laryngeal stenosis, acute nephritis, or paralysis. An experience extending over many years, in which we treated many cases of diphtheria, led us to believe that life is practically not in jeopardy except in laryngeal or kidney involvement. Also that it were a needless expense to use antitoxine in most cases, all in fact free from laryngeal or kidney invasion, as we always find nephritis early if at all and the same is true for the larynx; but recently we had a case of very severe paralysis, as a sequel of a very mild attack; therefore we have returned to the old practice of administering a single full dose—6,000 units—within the year; 10,000 units second year, in the mildest cases; though this practice is based on the one case of paralysis in a period covering from the introduction of serum therapy in diphtheria to the present time; but one were enough to justify a never failing use of the serum.

Therefore, guided by the lamp of experience, shining on our pathway, our refuge in laryngeal diphtheria, or membranous croup, if you choose, is in full doses of serum, repeated at intervals of eight hours, given for effect, doubling the dose if relief is delayed and in extremes we forget the units in a dose, but keep right on till victory crowns our efforts.

WHAT MUST WE DO TO BE SAVED FROM TEMPORAL DEATH?*

By REV. D. H. HOWERTON, Columbia.

I have exercised the right to change the subject a little and shall give a partial answer to, "What must we do to be saved from unnecessary temporal death?" or how may we prolong life?

I do not come to speak with the authority of a medical specialist, but the rather, to discuss some matters that are patent to the average layman.

I have injected into the subject the word, "unnecessary," because any preventable death is unnecessary. The answer to the question may be stated as follows: By preventing and holding in check disease and by avoid-

*Read before the Adair County Medical Society.

ing accidents or other things that would hasten death. I shall undertake to show how some of these death-dealing forces may be overcome and thus how to prevent the unnecessary.

But, as I see it,—taught both in Revelation and by observation, confirmed by experience—there is no ultimate escape from death. "Death hath passed upon all." "It is appointed unto men to die." So death, as conditions now exist, is a divine arrangement. But it is not provided that we shall hasten the divine plan by failure to prevent, or defer death as long as practicable. We have a divine appointment to die, but also a divine prohibition against taking our lives, or impairing our usefulness. And this prohibition carries with it the idea of caring for health, guarding against anything that may cause us to die, and thus of prolonging life up to, and, if possible, beyond the Scripture limit of three score years and ten. It also penalizes the one who fails to do all he may to prevent death as long as he can. And the penalty is to be seen, not only in the offender himself, but the iniquities of the fathers are visited upon the children of the third and fourth generation.

So death that comes early in life as the result of disease contracted through exposure, neglect or other violation of hygienic laws, or by any other causes that may be avoided, is unnecessary, preventable and renders the offender culpable.

Such a death is a three-fold offense, viz.: Against self, against the community and against God. Every man owes it to himself to live as long and as soundly in health as he may, in order that he may develop to the full his inborn powers, enjoy the pleasures of his environment and prepare for the largest possible life in the great beyond. He owes to the community a long and honorable career that he may bless his fellows among whom he moves and lead them into something noble and good. One has no right to kill himself or to shorten his life by any means that may be avoided. And he who does it, to the extent of his personal neglect, brings disgrace upon himself, his family and the country in which he lives. Particularly is this true of suicide. No one has a right to take, either his own, or another's life. To God who gave life he owes it to live as long and honorably as possible that he may glorify Him. Our lives are in His hands and He will take care of them; if we will let Him. But we must let Him by caring for ourselves as far as in us lies.

Now I am in the predicament of one of our pastors, a doctor of divinity, who was attending a banquet in the city. He had been addressed as doctor. His companion at the ta-

ble, not knowing his profession, asked, "Doctor, where do you practice?" The pastor replied, "I do not practice, I preach." I am neither a physician, nor the son of a physician. I fear I do not practice as I should. Certain it is that I am not what is regarded as a practitioner. But on the other hand, I am not "just preaching" now. I am in earnest and trying to give a few solid facts for earnest consideration.

We love life. We want to live. We do not want to die. The fact is, in the last analysis, we are all afraid to die. I do not believe a healthy, normal person ever does, or ever should want to die. But he should so order his life as to be ready to die at any time. In order to live and so prevent unnecessary death, we must observe God's laws for the prevention of disease, preservation of health and the prolongation of life. These laws are easily discovered, if not so easily obeyed. And they carry with them penalties that cannot be escaped if they are violated.

I mention three avoidable ways by which unnecessary death is hastened. These are exposure, intemperance and neglect. There may be others—in fact there are others, many of them. But these will suffice for this study.

Now, I did not solicit the privilege of making this address. But since, assigned to the task, I must give expression to my convictions. I am aware that I am touching delicate matters and treading on dangerous ground. But, you know, "Fools rush in where angels fear to tread." I dare to speak what I might perhaps better be afraid to utter. Concern, however, for the welfare of the community requires plain speaking. I am not the regulator of the community's conduct. But I am interested, both for the health and the morals. And this is a matter involving morals as well as hygiene.

By exposure, mentioned above, I refer to ones placing himself in a position where he is liable to injury or to infection from disease, either of which endangers life. No injury, of whatever nature or degree of seriousness, is ever so thoroughly overcome as not to interfere in some degree with one's life. We induce colds and their resultant diseases when we fail to exercise care as to clothing, and as to what we do and where we go in disagreeable weather. We lay ourselves liable to accidental injury and death when we come too near an object in which there is danger. We subject ourselves to infection when we do not avoid any, and all contagious or infectious diseases. In view of these facts, do not expose yourselves, that you may be saved from unnecessary death.

By intemperance, many things, other than the excessive use of intoxicating liquors, is meant, including this, however, I mention

intemperance in matters of clothing as well as in eating and drinking.

Now, I am not a director of fashion, nor do I presume to dictate how people shall dress. But I observe some hurtful things; against which, however, it seems futile to protest. Those who practice such things must suffer the consequences. Tight lacing and high-heeled shoes are both prolific of untold suffering and disease. They throw out of normal position vital organs and prevent their performing correctly their functions and thus induce disease, and not infrequently, even if deferred, cause death. I now mention the scantiness of clothing worn by women oftentimes. It is especially noticeable in the young women and girls. Who is to blame for it? The parents of course. Your children are committed to you for your care. You are responsible both for their life and health. You are guilty if you do not exercise a care that disease, due to lack of proper clothing does not set up. Many a beautiful girl has died of consumption and been borne to the grave, followed by the fond mother and friends who bewailed the sad lot of one bereft by "divine providence." It was not a case of divine providence at all. It was rather a case of culpable human imprudence that that brought a life prematurely to an untimely grave. We often hold up our hands in horror at the rapid increase in pulmonary trouble. We are now expending large sums of money for the prevention of this dread disease. I confess I am afraid of it. But, it seems to me we have begun at the wrong end of the matter to rid ourselves of this malady. It is a wonder that there is not more of it the way the girls are allowed to dress or rather to go so nearly undressed, especially in damp and wintry weather. What with bare arms and uncovered chests and low shoes in winter and early spring is to be expected but colds followed by lung disorders resulting ultimately in death? And, mark you, such death is but a case of suicide. And suicide is murder whether it be by a slow or quick process. And the murderer will surely be required to pay the penalty. And somebody's blood is, as surely, to be required at the hands of others because of deaths due to this silly craze for following the fiat of the framers of fashion. The days of human sacrifice are not over. We listen with indignant wonder at the recital of some missionary describing how a heathen woman casts her babe into the river Ganges to be eaten by the sacred crocodile, or another casts her babe into the flames as a sacrifice to the fire god. But, in this, so-called, civilized land, what of the young lives being daily sacrificed to the voluptuous goddess of fashion? I raise my voice in solemn warning and charge

the death of a great many of our girls to this very matter of intemperance in dress.

So much for that. I leave to the doctors to tell us what to eat and how. But suffer this incident. It illustrates a Bible doctrine and a law of health in the matter of eating. Several men were waiting at a village store for the mail to be opened. Behind the stove sat a man who was drunk and apparently oblivious to all about him. Another man, a preacher, by the way, remarked that he was uncomfortable because of having partaken too freely of a bountiful holiday dinner to which he had been invited. The drunkard straightened up in his chair and said, "Brother, You-and-me-is-in-the-same-box." The preacher asked how that could be. "Well," said the drunkard, "yon made a hog of yourself a eatin' and I made a hog of myself a-drinkin', and the Bible says that no drunkard nor glutton shall enter the Kingdom of heaven." There is to much of truth in his statement. We need to exercise a care lest more of us become gluttons and thus hasten ourselves to an untimely death.

So I urge that there is need for temperance in matters of clothing and food. I also call attention to intemperance in the use of tobacco. Cigarettes poison the system, dull the intellect, deaden the moral and spiritual sense and produce early death. The so-called soft drinks vended in almost every store in the country develop an appetite for opiates and intoxicants, and, as is well known, these hasten multitudes of premature deaths.

I merely mention the matter of neglect. Many a disease might be avoided or held in check but for the matter of neglecting these very things we are discussing. By a little neglect disease is allowed to fasten itself on the system and ere long another victim is claimed unnecessarily by the insatiable monster, death.

How may we be saved from temporal death? By so caring for the body that there shall be less occasion for appealing to the physician to remedy some fault we might have averted. But when occasion does arise for calling on the physician then follow his specific directions. By following the laws that are to be observed in your daily experience for preserving your own health and remembering that the body is the temple of the Holy Spirit and is therefore not to be defiled or otherwise marred in its powers.

WHAT HAVE THE HEALTH BOARDS DONE FOR THE COUNTRY!*

By U. L. TAYLOR, Columbia.

I am here to answer the question propounded in this program "What have the Health Boards done for the Country?" Without sickness we would have had no use for Boards of Health. In all ages of the world since the flood, we have been afflicted with diseases. I say since the flood, for before the flood there was no sickness. Then the people lived to be nearly one thousand years old, and died without a disease, or the help of a doctor. We read of but one young person dying before the flood, and he was murdered by his brother. Whether sickness was caused by the many millions of bodies of man and beast decaying upon the earth, at the time of the flood, we do not know. But it is certainly reasonable to so believe. At least after the flood we hear of sickness, and death following the sickness. But the length of human life was very much shortened. Moses lived to be one hundred and twenty years old, and died without being sick. And along about this time, we begin to hear of doctors. We are told that King Asa was diseased in both of his feet, and in his distress he sought not the Lord, but the physicians, and in the very next verse we have the sequel, and King Asa slept with his fathers in the 40th year of his reign. But the age of man continued to grow shorter. King David said, the days of our years are three score years and ten. A little later one of the prophets in highly figurative language said, "is there no balm in Gilead, is there no physician there, why then cannot the health of the daughter of my people be recovered?" Solomon, who succeeded David as King of Israel, mentions apothecaries. He said dead flies cause the ointment of the apothecaries to send forth a stinking savor. And this is not wondered at, but they at least got rid of the flies. But diseases continued to multiply, and that brought about a multiplication of doctors, and notwithstanding the multiplication of doctors, human life continued to grow shorter. At the time I commenced the practice of medicine, about 50 years ago, the average of human life was 33 years. And with all my skill and learning, I could make no material lengthening of the average. But a little later a very great change took place in the practice of medicine. The doctors seeing they were not a success in the curing of disease, undertook to prevent it, undertaking to prove the truth of the proverb, "an ounce of preventive, is worth a pound of cure." Several

notable efforts had before this time been made to ameliorate the condition of the human family, but it was always at the expense of the reputation of the ones that engaged in it. William Harvey had more than three hundred years before this time discovered the circulation of the blood. Physicians for a thousand years had been bleeding their patients, without an idea as to why they did it or where the blood came from. Dr. Harvey did not publish his discovery until he thought there could be no doubt about it, but he did not wait long enough. A great howl was raised about it, a mob gathered and he had to flee for his life to escape the mob. In his absence, the angry populace broke into his home, seized all his furniture and papers and burned them in the street. He remained away from home for six years, and by this time the whole world acknowledged the truth of his discovery and were now ready to welcome him back, and crown him with laurels, while he lived, and strew flowers upon his grave after he died. Two hundred years later, when smallpox was destroying thousands of the human family, and whole cities were being almost depopulated, William Jenner discovered vaccination. There was a great howl and kick made on the part of the great common people about this. It was perfectly absurd. The idea of taking serum from a cow and inserting it in a man's arm to prevent the taking of smallpox, was unthinkable. A mob was raised, and Jenner had to flee from his home, and be a fugitive until the second thought of the people caused them to investigate the subject, and prove the truthfulness of the claim. Then Jenner was a great man, and everybody did him reverence. But not until about 15 or 20 years ago, did health boards begin to organize, and get in their work. But their business was not to treat and cure disease, but to find out and remove the cause. And in doing this they found that nearly all diseases were caused by small and insignificant things. They found that yellow fever and all malarial diseases were caused by the bites of mosquitoes. They found that consumption and typhoid fever were caused largely by the common house fly. They found that bubonic plague was caused by the bites of fleas, and that the fleas were carried from place to place by rats and cats and poodle dogs. And these health boards have been for several years largely trying to eliminate these pests. A few years ago, when yellow fever was in New Orleans, and the local doctors could do nothing with it, some expert doctors from the Marine and Hospital Service from Washington, were sent down there, and they began, not by treating the yellow fever patients, but by driving out the mosquitoes. They succeeded, but not without loud howls from the great common

*Read before the Adair County Medical Society.

people. But the scourge has not been there since. Then, during the Spanish-American war, yellow fever was destroying hundreds of people in the city of Havana. And our Health Boards undertook to rid the city of the trouble. Havana had for generations been a hot bed for yellow fever. It was the starting point of all the epidemics that had ever visited the United States. Our Health Boards began as they had at New Orleans, by driving out the mosquitoes. Before this time strangers could not live there during the summer months. Now it is one of the healthiest cities in all the land. People visit it from all the countries as a health resort, to enjoy the sea breezes, the songs of their beautiful birds, and the perfume of their sweet smelling flowers without a thought of any danger from yellow fever. And then when our country got possession of the canal zone, and undertook to dig a canal through that pestilential country, our medical experts took the lead, and went down to prepare the way, for our army of occupation. They went not with picks and spades, but a full line of sanitary supplies. The French people had undertaken to build a canal through that unhealthy region, but had signally failed. Napoleon Bonaparte, one of the greatest military commanders that the world has ever known, always had, on the eve of a great battle, something inspiring to say to his soldiers, and when his legions were drawn up in battle-line at the foot of the great Egyptian pyramids, said: soldiers, forty centuries are looking down upon you from the tops of those lofty pyramids. There was not a man in that vast army that day who would not have given his life on that occasion for his beloved Emperor. And yet in less than one century, that same French people were driven out of Panama by mosquitoes. And after spending millions of money, and thousands of lives, sold out to the United States. They first killed and drove out the mosquitoes, then dug the canal. Panama is now one of the healthiest countries on the globe. A celebrated English surgeon, now traveling in the United States, whose name I have forgotten, says: "You may talk of your Niagara Falls, and your Mammoth Cave, and your fine buildings in the city of Washington, but the greatest achievement that ever has been accomplished in the world is the transforming of that canal zone from a hot bed of pestilence to a country that is as healthy as any upon the face of the earth.

These are a few of the things that the Health Boards have done for the country. But the hardest fought fight, and the most persistent fight has been made against the great white plague, or consumption. This is the greatest enemy that we have to contend against. More people die from this com-

plaint, than from any other disease. In the last five years statistics show that in the United States alone, 750,000 persons have died from this malady. This is fearful. The health boards have discovered that it is caused largely from sputum from diseased persons by promiscuous spitting upon sidewalks in cities, and in public places in the country, and that the carriers are the common house fly. But in the last two or three years, the disease has been giving way before the persistent efforts of the boards of health. In the last report of the National Tuberculosis Association I find the following: In the last decade, from 1900 to 1910, the death rate from tuberculosis in the United States declined from 196 for each 100,000 persons living, to 160, a decrease of 18 per cent., while the death rate from all causes of death declined only one half as much, or at the rate of 9 per cent. These figures were given out in a statement issued by the National Association for the Study and Prevention of Tuberculosis. They are based on data abstracted from the United States Bureau of the Census, and cover the registration area in the country. The decline in the tuberculosis death rate in the last two years, means a saving of 27,000 for each year.

WHAT HAVE HEALTH BOARDS DONE FOR KENTUCKY?

To answer this question would require more time than I can devote to it this evening. Kentucky stands high up in the scale of public health work. The health boards have driven out nearly all the quacks and charlatans. They have saved the lives of thousands of children by the war they have waged on adulterated milk from tuberculous cows; they have made an unrelenting war on consumption; they have made war on cholera in hogs and chickens; they have furnished thousands of diphtheritic children with antitoxin at a price that the poor can afford to buy it, thus saving the lives of thousands of children. They have appointed health boards in every county to look after the public health. They issue bulletins to all the people, instructing them on these fatal preventable diseases and are ready to meet epidemics wherever they may be found, and are at present in the front looking after the two new diseases which have only recently made their appearance in the state, pellagra and the hook worm disease. But I know more of the workings of the health board of my own county, than in any other. I have been the health officer for this county for the last twenty years. I did not from the beginning, where duty called, know any better than to go. I have for the last ten years been visiting every typhoid fever epidemic that sprung up in the county, and trying to

suppress it, right at the beginning. I have visited every case of smallpox that I could hear of in the county. For the last six years I have visited all the public schools in the county, and talked to the children on sanitation and right living. I have looked into the sanitary surroundings of every school house. I have given directions as to the location of every new school house that has been built. I have for four years visited and fumigated every house where consumptive, diphtheritic, or typhoid fever patients have died. These have not been done by the health officers in the surrounding counties. The difference between me and them is, they wait for the Fiscal Courts to promise them pay, and I go ahead and do the work, and at the same time compel the fiscal court to pay such a salary as will let me live. Now does all this work amount to any good to the community? Casey county pays her health officer one hundred and fifty dollars a year, and, of course, he cannot afford to give much of his time to the public health business. At the beginning of the last decade, Casey county had a population of 15,140, and gained during the decade 335. Adair county in 1900 had a population of 14,888, and gained 1,614. Metcalfe pays her health officer \$50, and had in 1900, 10,000 population and gained 455. Adair's death rate last year was only 13 to the thousand inhabitants, a better showing than can be made by any other community. Columbia's death rate last year was only 11 per one thousand. We have very few deaths among our young people. During the three years that our graded schools have been running, out of a total of 360 pupils, there has not been a single death.

In conclusion, I want you to excuse me for blowing my own horn. I would not have done it, but I had nobody to blow it for me.

SOME FACTS ABOUT SANITATION AND PREVENTIVE MEDICINE.*

By L. F. HAMMONDS, Danville.

I am with you to-night on a mission of health, not to tell you of some great thing that you have not heard, but to impress upon your minds the thing that your doctors have often told you. You have a noble set of doctors in your county, of whom you have a right to be proud, and you should ever be ready to join hands with them in any health movement they undertake, as they are ever ready to do anything that will better the health of your county, prolong your lives, eradicate disease from your county, make you a happier people and decrease their income and save you hundreds of lives and thousands of dollars.

There are many diseases that have no right to exist and should be and can be eliminated from the category of diseases, there are at all times 1,000,000 people seriously sick in the United States of preventable diseases. This state of affairs should not exist but will never be very much better until the medical profession and the people work together, but as it is, the medical profession finds it is handicapped by the people who are, as a rule, unwilling to aid in any way to work for their own interest and to decrease the income of the family doctor. Of all the professions the medical profession is the only one to work against its own interest, and yet at the same time it has to work the hardest to get the people to take their advice.

As I stated before, there are many diseases that should be prevented, and if the people will take the advice of the medical profession, these diseases will be known to the next generation only by history, and as things of the past. Among the many preventable diseases tuberculosis stands at the head with its death rate and expense. This is a preventable disease and has no right to exist as every case depends upon some other case for its existence. Every county should have a sanatorium for the treatment of this disease and many cases, properly treated, would recover and would make useful citizens and happy homes. Those that are incurable would be removed from society and prevented from infecting others, and not until this is done will the disease be eliminated, and when this is done and all cases, as soon as they are found to have the disease, will go to the sanitarium and remain until cured or relieved by death, in a very short time tuberculosis will be a thing of the past.

Typhoid fever is another preventable disease. By better sanitation and better care of those already sick, we can eliminate this disease from our county and thereby save us hundreds of lives and thousands of dollars each year. We should see that we have a pure water supply and also pure milk, as these are the most common source of infection.

One very common and most neglected source of danger is the ordinary house fly, or, as Dr. L. O. Howard, Chief of U. S. Bureau of Entomology, would have us call it, the "typhoid fly." Every case of typhoid should be isolated and placed in a screened room to prevent the passing of flies, as they will carry this disease for several miles.

Malaria is a preventable disease, this can be prevented by proper attention to sanitation. Keep all the stagnated ponds drained, or destroy the mosquito. This can be done by pouring oil on the ponds, and the stock ponds in the community should be kept in proper condition, or better not have any. One very

*Read before the Casey County Medical Society.

common source of infection is the ordinary rain barrel by the side of the house, which is often neglected and the mosquito is allowed to multiply in great numbers.

There are many other preventable diseases, but I have not the time to speak of them all and only call your attention to these few because they are the most common in your community.

How are we to remedy this state of affairs? This is the all important question. Formerly lawyers were employed to conduct law suits, but now all incorporations and shrewd business men employ them to prevent lawsuits. This should be true of the physician. Every family should employ a family physician, not only to treat their sick, but to keep them from being sick, and if this is done much sickness will be prevented and a great saving of life and money, not to say anything of the pain and sorrow. Every county should have a suitable health officer and pay him a sufficient salary to justify him to give his whole time to the work; no man can do his duty as a health officer unless he gives his entire time to the work. I am proud to say that you have a health officer that gives the work his entire time and study, but do you pay him a sufficient salary to justify him to do this? If not you should see that the next fiscal court raises his salary to what is right. The fiscal court in my county went on record (to its disgrace) and reduced the salary of its health officer from \$200.00, what it was last year, to \$150.00 and no county need to expect much from this amount as no one can afford to work for nothing. The best thing the voters of any county can do is to eliminate such men from our fiscal court, as men that have no higher regard for the health of their county should not be allowed to hold office, but should be relegated to the rear with the old fogies and moss-backs.

The people should ever be ready to take the advice of their health officer and help him in any movement he undertakes to better the sanitary conditions in his county; every person should look after the sanitation around his own premises, keep all ponds drained and everything as clean as possible and present, as far as possible, the decaying of vegetation around the premises, and above all keep the back yard in good condition. How many of you have mud and water standing in your back yard? and this even covered with a green moss and has a foul smell? How often do we see a front yard with everything attractive and healthful, and then pass to the back yard only to find the ducks and geese taking a swim in the mud and water. You often hear it said by some members of the family, "keep the front yard clean, but it does not make and difference as to the back

yard." This is not true as the back yard should receive the same attention as the front yard, and oftentimes more, as the sun does not always have the same access to the backyard as it has to the front; the sun is our best friend and we should not be afraid of it and give it access to all parts possible.

If we would live more in the open air we would be a more healthful people. As a rule, we all spend too much time indoors, and sleep with our bed chambers too tightly closed. If we would sleep with every window to our room hoisted, we would be more healthful. A laboratory should be established in every county and should be under the care of the health officer, and any citizen should be permitted to bring water, drugs, food, or anything suspected as dangerous, and this should be examined without personal expense to him. In this way much sickness can be avoided by finding out the source of infection; many old and honored wells are only a source of danger and should be filled and new ones drilled and arranged so as to exclude all surface water, the surface water is laden with poisonous germs. Another source of danger is the ordinary carpet. I long to see the day when they will be a thing of the past and their place filled with painted floors, or removable rugs, the painted floor is the best.

The medical profession has long ago recognized these dangers and the importance of sanitation and have been striving to better them, but so long as they are handicapped they can do but little good.

Whether you accept my message or not, you must acknowledge it as unselfish labor, as I am here at my own expense and the expense of my brethren who live by the treatment of disease, to proclaim the gospel of health and to cut down their income. If you will accept my message and come before your fiscal court with such a force that they will not dare to turn you down, and have them to pay your health officer a sufficient salary to justify him to give the work his entire time, and erect a sanitarium and properly equip it for the treatment of all infectious diseases, in a short time you will save, in the way of doctor's bills and the other expense caused by sickness, more than it will take to build and equip the sanitarium, and many diseases now common in your county will be a thing of the past and many lives and thousands of dollars will be saved.

George M. Gould estimated that the cost of sickness and death in the United States from preventable diseases will amount to \$1,000,000,000 annually, of which amount it is safe to say that you pay at least \$50,000, not to say anything of the pain and sorrow, which is

a great deal more than it would cost to put your county in good sanitary condition.

I hope that your county will soon come to the front and stand as a model to the world for health and sanitation.

PELLAGRA.*

By MONROE PENNINGTON, Bertha.

The scope of this paper will be limited to the etiology and treatment of pellagra.

The microorganism producing this disease and their mode of transmission is as much a mystery to-day as in the eighteenth century, when it appeared in Italy. As early as 1762 Casal attempted to elucidate the causal relationship between the consumption of corn and pellagra, and wherever pellagra has existed since that time, most medical men have attributed it to the use of maize. While many cast about for other causes, one after another of them fall into disrepute, and to-day, we face pellagra in the southern states with the maize product held up as the most prominent factor in the production of this disease. Experimental work done to show the cause of pellagra produces a toxic and a resinous substance of spoiled corn, such as exists in spoiled corn only. To one of these is attributed the relation of maize to pellagra. It also has been established that corn contains more oil than any of the cereals, the amount being as high as 9.5 per cent. Part of this oil being linolein, which is a compound of linoleic acid, readily undergoes fermentation or oxidation. It is interesting to know that cotton seed contains this same oil and that all seeds containing linolein easily undergo decomposition. With these facts in view we might blend the two prominent theories and wage war on both the corn growers of the west and cotton raisers of the south—but when statistics from different states are considered we are reluctant to say that these products are more than contributory factors in producing pellagra. To assert that pellagra is not contagious or infectious because no special organism has been isolated, which produces it, would open up for scientific discussion the question as to whether measles, mumps or scarlet fever are contagious, no organism having been found to produce either of these diseases.

To support the theory of some form of direct transmission we cite seventeen cases in the Baptist Orphanage, at Nashville, Tenn., ten cases in one family of eleven in Waycross, Georgia. One case was diagnosed on Straight Creek, in Bell county, in the spring of 1910, ten months later 50 cases were reported within a radius of two miles. At Wilton, Knox county, one case was found in the summer of

1910, during the next 12 months twenty cases developed within a radius of one mile. Near Corbin, in Laurel county, a woman died of this disease in the spring of 1911, the following fall her six year old daughter developed a severe type of the same. During the summer of 1911, three cases were seen in each of two families and four cases in another in Whitley county. I observed three sisters in the same community, each suffering from pellagra, two of these women had daughters suffering with the same malady. In another instance two sisters were effected with pellagra, one of them had a daughter and a granddaughter likewise afflicted, all three occupying the same house.

Bacteriologists have found that diphtheritic bacilli are best cultivated on a media of blood serum. Typhoid bacilli are best grown on beef bouillon and the spirochaete of syphilis is produced on blood plasma, while pneumococci grow on agar, serum, potatoe, milk or most any of the ordinary culture media. We note the different cultures necessary to produce active microorganisms of different diseases, so it may be understood that linolein oil or other constituents of corn having undergone fermentation or oxidation as it may do in the body, prepares the media which renders the reception and growth of the micro-organism of pellagra possible, making the persons with bad hygienic surroundings and those who consume great quantities of corn products much more susceptible than those whose resistive powers are greater and who eat less of the corn products. We will imagine that this microorganism will multiply outside of the body in warm climate and that it has small power of resistance when subjected to low temperature and that it is wide-spread throughout the community in which it exists. The reason pellagra is not more epidemic in nature, being the high power of resistance maintained by a majority of the people. It does not appear logical to say it is produced by corn products, let them be bread, cornstarch, candy, syrup or cereals, assuming that the corn-products producing this disease are spoiled, as the disease has increased rapidly under the Pude Food law of 1906, since which time all articles of food have been inspected and every effort made to bring them up to the highest standard of purity, so we conclude that there is one mode whereby the disease is transmitted directly from the infected to the susceptible. The investigations now being made in the southern states will no doubt result in the isolation of the micro-organism and demonstrate its effect as Koch did the tubercle bacilli. Klebs and Loeffler did the diphtheria bacilli and Eberth did the typhoid bacilli. Until this discovery is made we will be treated to new and varied causes of the

*Read before the Knox County Medical Society.

disease from time to time, but this shows that active work is being done and we should study all of the literature coming under our observation pertaining to this dreaded disease.

The lack of cooperation keeps many lines of treatment before the profession. If all men who treat pellagra in Bell, Knox, Laurel and Whitley counties would attend and report their cases treated and results before their respective county societies and these societies would compile these reports it would make a tangible base as to results of treatment. I am convinced that calcium sulphide has acted better than any drug I have used in early cases, and think if it is used persistently with good hygienic surroundings and plenty of good nutritious diet, along with such symptomatic treatment as the individual case may require, such as lotions for the skin, palliative treatment for gastro-intestinal disturbances and avoiding excessive exercise or exposure to direct rays of the sun. The mortality will evidently be lower in cases which receive treatment from the first appearance of the cutaneous lesions. I have also found arsenic to be of service when used in the advanced cases of this disease.

DYSENTERY.*

By CHAS. L. HEATH, Lindsay.

Dysentery is a specific febrile disease, marked by inflammation and more or less bowel trouble, accompanied by pain, tenesmus and mucous, bloody stools frequently occur in epidemics, in small infants may, first notice restlessness, inability to sleep as well as usual, nurses very little, and appears to be in distress, vomits milk which has a sour smell. Soon after, or perhaps without, these symptoms, the diarrhea begins with other abdominal symptoms such as swelling, soreness and pain with more or less fever.

In children of more advanced age the disease may come on abruptly, or may be a few days before it fully develops, but usually the doctor does not see the little patient until the mother has exhausted all the family remedies without success, and by this time we generally find a picture that is not hard to read, from the fact that in no other disease do we see such pain and distress at each evacuation of the bowel, bloody mucous often being discharged with considerable pain and as often as 30 to 90 times in the 24 hours.

As it is not hard to diagnose the old time flux of our young days, the treatment is often not such a simple matter. To begin with our patient should have careful supervision during the winter and spring months, so that any irregularities of the alimentary tract may be

remedied before they have attained such headway as is usually the case when we see our cases of flux for the first time.

Now one thing that speaks well for the efforts that have been made by our workers along preventive medicine, is that we are seeing less of such summer diseases and that you don't see so much in the journals regarding these old time dreaded diseases of the country practitioner, we no longer have to wait until frost comes to get relief for our little ones, we begin by having all things in such favorable condition that this disease, so fatal a few years ago, no longer visits our homes with such frequency or fatal result.

When we first see our patient a good plan is to give castor oil and to use colon tube with saline solution at 100 to 105 degrees F., if this is not well borne discontinue, but when bowels are not very active the saline solution once or twice a day will do good. Calomel is good if oil is not well retained, and for the pain and excessive discharges opium in the form of Dover's powder is to be given to effect.

Rx.

Bismuth subnitratezv
Syr. rhei aromaticiziii
Aqua, q.s. adzlv
Sig. One teaspoonful every two hours.

If the bismuth does not turn passages black give one grain doses of precipitated sulphur with each dose of bismuth, also if Dover's powder is given it may be added to each dose as given.

The old time starch and opium will be of service in cases of much tenesmus with small amounts of blood-streaked mucous, for a child under one year:

Rx.

Starchzii
Boiling waterzii
Tr. Opii5 gr.

Repeat in six to eight hours.

The question of feeding our little patients with acute dysentery is of too great importance to try to discuss it in this short paper and I will refer you to the text books on feeding for full directions for preparing and administering food; make a careful study of each case and adopt the diet best suited to the case, but remember that in no place does the old adage that, "a stitch in time will save nine," fit in better than where we use all means at our command to prevent summer diseases of the bowels, especially in infants.

*Read before the Knox County Medical Society.

THE NEW THERAPY OF SYPHILIS.*

By D. H. MCKINLEY, Winchester.

When Metchnikoff and Roux successfully inoculated the higher apes with syphilis in 1903 a new era in the history of this disease was inaugurated. In 1905 there followed the discovery of the specific microorganism by Schaudinn and Hoffman, to which the name of *spirochaeta pallida* was given, but afterwards changed to that of *treponema pallida*. Another great step was taken by Wasserman in 1906, when he introduced his sero-reaction. Our etiology, pathology and diagnosis was now complete, but in the field of treatment much was lacking. The crowning event of this series of brilliant achievements came in 1910 with the production of salvarsan by Ehrlich. It is a wonderful thing when we consider that in the short time of seven years, the whole subject of this disease, which has cursed humanity for centuries was brought from the dark abyss of ignorance and laid bare before the light of modern science. There is nothing more spectacular in medical history. Of all the afflictions which flesh is heir to none has been held in such holy horror as lues, and at the same time none has been so cruelly neglected or so mistreated.

Before the discovery of "606" we had two drugs, mercury and the iodides, while inferior to it in every respect, could still be relied upon to cure practically all cases. But the trouble was that we didn't use the weapons we possessed in the proper way. I feel safe in saying that up to the last year or two probably 90 per cent. of the doctors throughout this country relied entirely upon internal administration. I believe that extremely few cases are ever cured by such indication, and as a proof of its ineffectiveness, I call to witness the vast army of paretics and ataxics, and those hopeless and helpless individuals who crowd our state institutions, who have been fed on protoiodide pills in the vain hope of producing a cure.

Thousands of poor unfortunates have been the victims of still greater mistreatment, being given only syrup of trifolium compound or some syrupy mess of sarsaparilla. I know physicians, enjoying a large practice, who in this present day of supposed enlightenment, never give a syphilitic anything but potassium iodide.

Undoubtedly this disease has been and still is woefully mistreated in many quarters. Mercury, to be effective, should be given in one of three ways—by intravenous injection, by inunction, or by intramuscular injection. The first is impracticable and to some extent

dangerous, the second is efficacious but a dirty and disagreeable treatment, the third I regard as the method of choice, and of all the preparations that I have used for intramuscular injection I prefer a 10 per cent. suspension of the solution of mercury in benzoinol or liquid alboline. Giving on an average of 15 m. once a week. Since the advent of the Wasserman reaction we realize that even after the most energetic mercurial treatment, fully half of the patients discharged as cured are in reality latent syphilitics.

My first experience with "606" was in November, 1910, when I had the pleasure of watching the results attained in a number of cases in New York by Dr. Jno. A. Fordyce. At that time only the intramuscular method was being used. My first opportunity to employ it in my own practice was on January 4th, 1911, when I gave two secondary cases 6 gm. each by intramuscular injection of alkaline solution. The following week a case with pronounced tertiary lesions received the same treatment. Since this time, however, I have used only the intravenous method, employing the apparatus devised by Heidensfeld for this purpose, and have treated the following 33 cases: 1 primary, 1 of malignant syphilis, 12 presenting active secondary lesions, 9 presenting active tertiary lesions, and 10 of latent syphilis of from 6 months to six years' duration. Two of the secondary cases, in both of which mercurials were discontinued, showed a return of a positive Wasserman, one in four and the other in five months. They were given a second dose of salvarsan and mercurial treatment instituted and kept up for six months, the reactions of both have been negative for five months now without treatment and I regard them as cured.

In the malignant case the results were brilliant but temporary. This patient had an infection of four months duration of a most malignant type, with a severe iritis. All symptoms had vanished within a week, when I lost sight of the case, but he suffered a recurrence five months later.

These are the only cases that have shown recurrences.

In none of my cases has salvarsan failed to produce a prompt symptomatic cure and in none have there been bad effects of any sort. I don't propose to bore you with a detailed account of the technique of the intravenous injection, but wish to mention one or two practical points. For instance the introduction of the needle into the lumen of the vein (not always an easy matter for the beginner) may be rendered much easier by dipping the point into sterile olive oil just before we are ready to insert it. I always use freshly distilled water to make up the salt solution, but

*Read before the Kentucky Valley Medical Association, Torrent, June 25-26, 1912.

after the saline tablets have been dissolved in it, I have invariably found little pieces of fiber and particles of extraneous matter. I have used four different brands of tablets and found this trouble with all. For this reason I allow the solution to stand for several hours and then siphon off the top into a flask, which is then sterilized by boiling. Instead of the normal salt solution I have been using a solution of only half strength and find that it is less apt to produce a chill and nausea. With a perfect technique I believe the intravenous administration of salvarsan is devoid of danger, and is the treatment to be employed in all cases unless specially contraindicated. We should not rely solely upon it, however, but should combine with it, either mercurial inunctions or injections of mercury salicylate, and to be on the safe side repeat the salvarsan in four weeks. In this way I believe it entirely possible to permanently cure the average case of lues in from three to nine months. In cases of long standing it is probably advisable to give a course of the iodides preceding the salvarsan, in order to aid in the absorption of infiltrations and opening up the lymph channels, in this way endeavoring to reach the more or less isolated foci of infection. After an intravenous injection a large part of the salvarsan is excreted in the first 24 hours, a small amount in the next 24, while the remainder is stored up in the internal organs, principally the liver, and I wish to call attention to its tonic effect, it is far beyond that of any other drug which we possess. It is nearly always followed by an increase in weight, strength and appetite and a great improvement in the mental and general physical condition of the patient.

What are the contraindications to its use—very briefly they are advanced cardio-vascular degeneration and advanced degenerative changes in the brain or spinal cord.

Given a case of primary lues, what should be the proper method of procedure? First a positive diagnosis should be made by finding the treponema pallidum. Where possible the initial lesion should be completely excised and an antiseptic dressing applied. An intravenous injection of from .5 to .6 gm. of salvarsan, according to size and sex, should be given at once, and repeated in four weeks. Beginning after the first dose of "606" weekly injections of mercury salicylate should be given for four or five months, and then followed by the administration of potassium iodide, not iodolbin or sapodin, but plain old K. I. for one month. All treatment may now be stopped and we can be governed entirely by the Wasserman reaction. If a patient shows a negative Wasserman four to six months after all treatment has been stopped he may be regarded as cured.

Any person who has ever had a specific infection, no matter how long the interval since the initial lesion or what the treatment, should be regarded as a latent syphilitic until proven otherwise by a negative Wasserman.

I mention sodium eocdylate merely to condemn it, it has been widely advertised and extensively employed in some quarters and because of the arsenic contained it does sometimes clear up the cutaneous lesions. But it is in no sense curative of lues and has absolutely no effect on the Wasserman reaction.

From my own experience and from what I have read of the experience of others, I have reached the following conclusions, that salvarsan is by far the most potent remedy we possess for combating specific infection—but that one dose, neither preceded nor followed by mercurials—will cure only a small per centage of cases. That the internal administration of mercury cannot be relied upon, and should be used only in the intervals between the more vigorous courses of inunctions or injections. That the iodide of potash has little or no direct action in destroying the treponemata, but it does cause the absorption of the new growths or infiltrations produced by the spirillae—it is therefore indicated only in the later stages, and that in the Wasserman reaction we have the only reliable means of determining when a cure is accomplished.

PLACENTA PREVIA; DIAGNOSIS AND TREATMENT.*

By T. W. STONE, Bowling Green.

By placenta previa, is meant the attachment of the placenta in the lower segment of the uterus. It varies from a central to a small margin and may be expelled in front of the child.

It was recognized by the earlier obstetricians at that time being called "unavoidable hemorrhage" as opposed to "accidental hemorrhage" which occurs in the course of a normal labor. Its estimated occurrence is 1-1200, but so many are undiagnosed, it is doubtless much greater, perhaps 1-400.

The cause is not clear but we know that any inflammation of the lining membrane of the uterus will predispose to it; the ovum, not finding suitable lodging place in the usual site. Hence the large proportion found in multipara as compared to those in the primipara, for it is in such cases that we more often find endometritis and similar affections. The usual place of fertilization of the ovum is in the fallopian tube and by the time it reaches the uterus its trophoblast become active and

*Read before the Tri-County Medical Society, Bowling Green, April 9, 1912.

it at once burrows into the mucous membrane of the fundal portion of the organ. Should this be delayed until the ovum reaches the lower segment, it is not unlikely that it would attach itself in that zone and cause a serotinal placenta previa. If there is a proliferation of the uterine membrane to receive it, its growth may produce a separation and cause hemorrhage or an abortion. I dare say that a large proportion of early abortions are the result of misplaced placenta and are never diagnosed.

Repeated hemorrhage in the latter part of pregnancy makes an almost certain diagnosis of placenta previa. On examination, the cervix is found boggy and the presenting part can be made out.

The hemorrhage if at term occurs early with unruptured membranes and feeble pains or their absence altogether. Bleeding is more profuse as the pains pass off. During its height it may cease altogether from the pressure of the presenting part on the inter-uterine contents. The fetal mortality is from 50 to 60 per cent, and that of the mother, 10 to 12 per cent, which makes it an exceedingly interesting condition.

The treatment is still a much mooted question and we are looking anxiously for something that will lessen the high mortality. The high death rate is not alone due to the hemorrhage, but also to the complication that arises during and after delivery.

Each case must be treated on its own merits, and according to conditions existing in each particular instance. If hemorrhage is slight rupture of the membranes may be sufficient, the descending part plugging the bleeding vessels; this can be better accomplished by applying the forceps if dilatation is sufficient. The tampon is useful in a few instances, podalic or combined version is more, and Caesarean section has found some ardent advocates since the advent of aseptic surgery.

The recognition that the uterus should be promptly emptied has perhaps done more than anything else to lessen the mortality of the mother.

The danger of placenta previa should be recognized as in ectopic gestation and be treated by prompt and early action, for it is that obstetrician who considers least the life of the child who has the smallest maternal mortality.

The elimination of the sources of infection do much towards keeping down high mortality rate, and it is here that the objection to the tampon has been raised and has caused it to be discarded, almost altogether.

In a large majority of cases, version and a slow delivery is the best procedure. Follow this by prompt control of post-partum hemorrhage by packing the uterus with sterile

gauze, and the administration of saline to remedy the ill effect of loss of blood. I believe that by prompt treatment and meeting complications by the best modern methods that the maternal mortality can be reduced to 5 per cent. Caesarean section will increase the chances of the child over those delivered by the natural passage, but it can only be successfully performed in a well equipped hospital in the hands of competent surgeons and at a greater risk to the mother.

The indications for it are: 1st. When the mother is in good condition and not exhausted by labor or hemorrhage, and is willing to take larger risk upon herself to secure a living child.

2nd. The central implantation and the cervix undilated and undilatable. Early diagnosis and prompt surgical treatment by Caesarean section before the patient is exsanguinated is a Utopian fancy born of inexperience. If we recall our summons to these cases, we will remember that many of these are already exsanguinated when we reach them. We do not have the opportunity of an early diagnosis and, this fact alone excludes a large number of these cases from surgical treatment.

Speaking as I am to very few who have hospitals at hand, and where a competent surgeon can be had, I feel it worth the most to you, for me to dwell on a treatment suitable for the general practitioner.

There are three conditions that should govern our procedure in any case:

1st. The state of cervix; 2nd. The situation of the placenta; 3rd. The degree of hemorrhage. When we diagnose a partial placenta previa with moderate dilatation of cervix, it is only necessary to rupture the membranes and apply forceps and draw the head into the pelvis and thereby stop the flow of blood until delivery is complete. If the os is not sufficiently dilated to admit the forceps the membrane should be ruptured and a hydrostatic bag introduced into the annion which when being properly filled will make sufficient pressure to prevent hemorrhage and at the same time cause more rapid dilatation. Some traction can be made on it if necessary. The bag, like the tampon, is fruitful of sepsis and being difficult for an inexperienced operator to apply has only a small field in treatment.

In cases of undilated cervix with a central implantation of the placenta as soon as the cervix can be dilated, version is the ideal treatment. If it is at term or nearly so, it is usually announced by profuse hemorrhage and the cervix is, as a rule, sufficiently dilated to admit two fingers. I have never seen such a case without there being that much dilation. In this condition increase the dilation by manual manipulation and proceed to do it

version. The cases of central implantation are most serious, from the standpoint of hemorrhage, both during and after labor. Here the proper thing to do is to waste no time with tampons and bags, or any other mode of artificial dilation, but unnnally dilate sufficient to bring down a foot until the knee presents at the vulva and thereby plug with the hip.

After this, delivery should be slow for the lower segment of the uterus is thinned by the placental attachment, making it easy to rupture, thereby adding post-partum hemorrhage from lacerations of the cervix. If hemorrhage persists, gentle traction on the foot may be made, without injury, until dilation is sufficient to complete delivery.

Where the loss of blood is great, you should use saline infusion early. The best time to do this is after you have done the version and while you are waiting for better dilatation. The mortality rates given at the beginning of this paper are based chiefly upon hospital practice, and are greater than those in private practice, owing to the fact that so many patients are brought in who are already exsanguinated and with but little hope of recovery. Many of the children are delivered before they are viable even if delivered alive. However, the mortality is very high and the object of our treatment should be to bring it as low as possible. The shock is in direct proportion to the amount of blood lost, hence anything that will reduce the hemorrhage or build up the patient after it has occurred will fill the most important indications in treatment.

The following suggestions will form the basis of treatment:

1st. Prevention and counteraction of shock.

2nd. Checking hemorrhage.

3rd. Promoting uterine contractions.

4th. Facilitating uterine dilatation.

5th. Expedite delivery.

6th. Prevent accidents and complications.

EARLY DIAGNOSIS AND TREATMENT OF ARTERIOSCLEROSIS.*

By M. M. Moss, Bowling Green.

It seems that the thought that is uppermost in the mind of man is, to live, and extend his longevity to the longest period of life attainable. And the thought which is most repulsive to him above all others is, that he must die. Even when he has long since passed his allotted time of three score years and ten, and his waning vitality has reached its lowest

state of existence he clings with unabating tenacity to the brittle thread that is almost rent asunder, when the dream of his life is still to live. This being true, it is strange that the machinery of life, which is fraught with unparalleled complexity and delicacy of vital structure should be neglected and abused until it has assumed a state of permanent or premature senility. It matters not how late in life the fatal issue may come to a victim of arteriosclerosis, I take the position that his death is premature and that he would have lived many years longer had he taken such precautionary measures as to have prevented or deferred the development of this disease. The disease had its origin perhaps in Adam when he became an old man; since which time it has raged with unabating fury in every country and clime wherever man was found. It has been more disastrous to the human race than all the wars of every country combined, because it has existed every where and at all times. It has claimed more victims by far, than Asiatic cholera. The ravages of yellow fever pale into insignificance from a mortality point of view, when compared to that of this disease. I admit with regret, that the medical profession has been delinquent in its study to this class of patients, or to say the least, we have not given the attention to the early diagnosis and treatment of this disease that its importance demands. I recently met a man seventy years of age on the street and asked him in regard to his health. He said he weighed more than he ever had before and that he had never felt better with the exception of slight shortness of breath; he also mentioned some slight cerebral symptoms. I felt of his pulse and found it to be hard and unyielding. I requested him to go to my office and I took his blood pressure, which showed a systolic pressure of 225. While this man felt secure in his physical condition and it had not occurred to him to consult a physician, he attributed his slight discomfort to increase in flesh and age. He was really entering the stage of broken cardiac compensation and was at that time in imminent danger. Under appropriate treatment the symptoms subsided, and if he will keep himself under the observation of a physician I see no reason why he should not live many years longer. I mention this case to show the importance of not waiting for patients to present themselves for treatment, and how one may be advanced in the disease before he realizes the gravity of his condition. This is not by any means a disease that is found only in advanced age. It is not unusual to find it at any age past fifty. Within the past three years I have had three patients to die with angina-pectoris, all of whom had arteriosclerosis and were under fifty-five years of

*Read before the Tri-County Medical Society, Franklin July 9, 1912.

age. I know a lady of forty who has marked arteriosclerosis, she has had cerebral symptoms with evidence of broken cardiac compensation.

As the caliber of the arteries are diminished and the elasticity of their walls impaired, a greater force is required on the part of the heart to propel the blood through the arterial tree. This demand is met by a compensatory hypertrophy of the heart muscles as would be the case in any part of the body where a group of muscles were required to do extra work over a long period of time. So gradual is the process that the patient for a long time is not aware of the pathological condition that is going on within his system and which is bringing about gradually, irreparable changes in his vital organs; Hence, arteriosclerosis is a disease, the early stages of which is without symptoms, of which the patient is aware, and for which he is not liable to consult as until the disease is far advanced. This being true, it is our duty, and one I fear we have sadly neglected, as guardians of the health of the people for whom we practice to impress on those whose ages are past fifty the importance of an early diagnosis of arteriosclerosis. We should explain to them the frequency of its occurrence and make them understand the disastrous results that awaits them in their declining years, should they neglect having an early diagnosis made and receive appropriate treatment. As the early stage of this disease is without subjective symptoms, we are almost sure not to make an early diagnosis if we do not request the patient to be examined, and with timely advice and treatment we can very much enhance his prospects to live to an advanced age. Hardened arteries, increased arterial tension, left ventricular hypertrophy and marked accentuation of the aortic second sound, form a group of symptoms which leave no doubt as to the existence of this disease. In this disease as in the case of all others, prophylaxis is of the highest importance. To be successful in this we must have the co-operation of the public; and we cannot hope to secure their hearty cooperation unless we appeal to their intelligence. We should teach them the evil effects of the excesses of life and the disastrous results that follow in their wake, should they so continue to indulge. As early impressions are the most lasting, I believe that children should be taught in their schools that the human system is a delicate organism and requires the greatest care and attention that it may subserve the best purpose. That it is very susceptible to abuses in the way of excesses in the manner of living, which is undoubtedly the cause of so few people living to an advanced age. I do not believe the State could make a more judicious expenditure of money or conserve life

to a better purpose than to support a journal edited by experts on prophylaxis, and sent into every household, teaching people how to live, to avoid this and other diseases. There will come a time, sooner or later, in the history of these cases, when compensation will no longer meet the demand placed upon the heart, because of high blood pressure, at which time the left ventricle, because of a lack of force, is unable to completely empty itself, at each pulsation there is a residue, at the same time the left ventricle is receiving its normal amount of blood from the left auricle and there can be no escape backward as long as the mitral valves are intact; as a consequence the accumulation in the left ventricle becomes excessive and dilatation without treatment inevitable. If the dilatation is interrupted there develops a relative insufficiency of the mitral valve with regurgitation which is followed by a train of symptoms usual in broken cardiac compensation. With this it can be seen that the most important indication to be met especially at this stage is high blood pressure. It is too often the case that patients continue with this disease undiagnosed and untreated until they reach the stage of broken compensation, when we have at our command remedies that will prevent it or at least defer its development to a late period of life. I would enter a protest against those who would deery the use of drugs in this disease. For in all of my experience in the treatment of diseases, I have never met with more brilliant results, where the heart was not irreparably injured and as a consequence other organs seriously damaged. In the treatment of these cases each case must be a law unto itself. The same case will require a different treatment at a different stage. We must realize that we have a delicate and complex organism which is functionally impaired and which requires judicious adjustment. One of the causes of high blood pressure, as has been mentioned, is due to the diminished caliber of the blood vessels. In the reduction of high blood pressure we have a reliable remedy in nitroglycerine which has a two-fold action, that of increasing the heart's action and at the same time dilating the peripheral vessels. In the dilatation of the peripheral vessels one of the most important factors in maintaining high blood pressure is removed. While the effects of nitroglycerine is transient and will not last more than thirty minutes or an hour, the relief it affords the heart by dilating the peripheral vessels and giving more space for the blood to be contained in the arterial system, thereby enabling the left ventricle to completely empty itself at each systole, gives a chance to bring into action its reserve force and maintain compensation. This will be the case even though the brief

periods of relief from high pressure be experienced three or four times during the twenty-four hours of the day. The relief experienced from the use of the vaso-motor dilators sometimes extends over a long period of time after the withdrawal, due to the fact that during the time of removal of high pressure the heart has regained a great deal of its original tone, which enabled it to maintain compensation sometimes for quite a while. It has been my custom when I first see these cases to put them on 1-100 gr. of nitroglycerine in tablet form to be taken every four hours and continue this for a week or ten days, at the expiration of which time the blood pressure will usually have been reduced to practically its normal standard. I then put him on 3 1-2 or 4 grain doses of nitrate of soda, to be given three times a day and continue about three or four weeks, varying the size and frequency of doses according to the results obtained. If at the expiration of this time his blood pressure is within the neighborhood of normal, I put him on from 5 to 10 grains of iodide of potash to be given three times a day and continued for six weeks or two months. At this time if the blood pressure is under control, I withdraw all medicines given for this purpose and watch for the return of high pressure. In our eagerness to control blood pressure we should not lose sight of the fact that the patient's general condition requires careful consideration, that his nutrition should be maintained to its highest standard. The food taken should be at regular intervals, and not in excess of his powers of digestion and assimilation. This amount is highly important, it is equally as important that he should not receive more. Bodily fatigue and over-exertion should all be avoided. While moderate exercise, when the blood pressure is under control is beneficial, he should turn over his active business duties and care to others and at all times abstain from over-mental exertion. He should curb his ambition to excel in whatever line of business he has chosen to follow and content himself in the sphere of mediocrity. If we can convince him that in this he chooses between life and death, we may succeed in getting him to take our advice and he may live to an advanced age, otherwise a fatal termination is only a matter of a short time. To illustrate the beneficial results obtained from treatment, I will mention the case of a gentleman who came to my office about six months ago. He was seventy-six years of age. For several days prior to this time he had experienced a numbness on the entire left side of his body, the reflexes and sensations were intact, the motor functions were somewhat impaired, he suffered considerably with vertigo, had partial aphasia, with cramps in his legs at night. His arteries were hard and

he showed a systolic blood pressure of 240, at the expiration of ten days under the nitroglycerine treatment his blood pressure went down to 180. I then put him on nitrate of soda which he took for three weeks, showing a blood pressure at this time of 160. I then put him on the iodide of potash which he took for six weeks, at the expiration of which time his blood pressure was still 160, which is not high for a man of his age and condition. It has now been between three and four months since he has received any treatment. He is still relieved of the symptoms from which he suffered. While on blood pressure I wish to emphasize the importance of the use of the sphygmomanometer as we have no other means of determining correctly the amount of pressure. We can much better afford to dispense with the thermometer in fever than we can with this instrument in the treatment of arteriosclerosis. Digitalis has a two-fold action on the circulatory system, that of increasing the heart's action and contracting the arterioles, both of which are contra-indicated in high blood pressure; yet it may be given with decided advantage with failing ventricles and low blood pressure. It is best in these cases to overcome peripheral resistance by administration of nitroglycerine. It is claimed by Baldfour and others that digitalis cannot be safely given to senile hearts without simultaneously unblocking the arterioles.

ASCITES; DIAGNOSIS AND TREATMENT.*

By F. E. McCann, Gold City.

The symptoms of ascites briefly are: History of some heart, kidney or lung disease. There is an accumulation of fluid in the peritoneal cavity, on percussion we get dullness in the flanks with central tympany, changing with change of position of patient. In most cases fluctuation waves are noted on bimanual manipulation. In the female the vaginal vault is encroached upon as the fluid accumulates. The aspirated fluid in ascites is transparent, of low specific gravity, generally below 1012 with small amount of albumen. In rare cases the fluid may be white due to leaking of chyle into peritoneal cavity.

A number of pathological conditions may simulate ascites and thus complicate the diagnosis.

In examination of a suspected case the bladder should be emptied, thus eliminating a distended bladder as a complicating factor.

Hydronephrosis, develops more on one side with pain and tenderness in region of kidney.

In chronic peritonitis with effusion the

*Read before the Tri-County Medical Society, Franklin, July 9, 1912.

fluid is more limited, change in area of dullness with change of position less marked, due to adhesions. There is also tenderness and the fluid contains more albumen and is of higher specific gravity.

Of all the conditions that require a close differential diagnosis, from ascites the ovarian cyst is the most similar. In cyst the enlargement of the abdomen increases in height rather than breadth as does ascites. One side of the abdomen distends more than the other and the navel is less prominent.

In ascites, percussion gives dullness in both flanks with central tympany. In cyst we seldom find dullness in but one side with dullness in the center of abdomen also. The upper margin of the dullness in cyst is convex while in the condition under discussion we have a concave line.

The change of position of patient does not cause so marked a change in position of fluid in cyst.

On examination through the vagina we find no bulging on its walls, the uterus seems drawn up and is not so movable.

If the fluid be withdrawn and subjected to chemical and microscopical examination certain differences will be found that almost clinch the diagnosis. In ascites the specific gravity is less than 1012 while in ovarian cyst the fluid is always 1020 or over. In the ascitic fluid we have less albumen than in the other.

The microscope reveals great numbers of granular fatty cells, cholesterol plates and small pale granular cells in the fluid from ovarian cyst. The small granula cells or "ovarian cells" as they are often called, are considered diagnostic.

Some consider the treatment of ascites is solely the treating of the underlying condition. This is well and good and is our first duty to the patient but what I wish to give most time to is the condition itself.

It has been my good fortune to treat several cases of ascites since entering upon practice, and the treatment I give has acted best for me in these cases. The amount of fluid ingested is limited, and a rich albuminous diet advised. Iron phosphate to increase the nutrition of the blood and calcium lactophosphate to increase the strength of the cell walls. The bowels are cleansed with saturated salt solution.

When the amount of fluid is increasing rapidly compound jalap powder with bitartrate of potassium or elaterium is prescribed to produce free watery catharsis, the patient being watched closely for signs of exhaustion. I have used apocynin gr. 1-3 every two hours with fine results in cases not too far advanced. The nice action of this drug has given it

the name of vegetable trocar as you remember.

When the amount of fluid is great enough to cause discomfort the trocar and cannula is used to remove a portion of the fluid.

A better method now used extensively is maintaining drainage by inserting a catheter or drainage tube, fixing in place by zinc oxide adhesive. The tube may be clamped by forceps to permit removal of fluid at will or if patient is confined to bed the tube is allowed to drain into the proper utensil. This kind of drainage can be kept up for weeks, if the circulation remains good. Improvement of the underlying condition has resulted from this treatment in many cases.

In ascites from hepatic cirrhosis the surgeon has benefited a small per cent. of cases by establishing better drainage between the portal and systemic circulation by attaching a piece of omentum about two inches square to the abdominal wall, with catgut. Also adjacent surfaces of the peritoneum over the liver have been scarified and made adhesive to produce this result.

THE PRACTICAL, CLINICAL ASPECTS OF ANAPHYLAXIS.*

By N. C. WITT, Franklin.

Before dealing with the practical clinical side of anaphylaxis we will devote a few moments to a definition of the term and to its theoretical explanation.

Its meaning in the simplest form, is something antagonistic to the protection of the animal.

Rosenau and Anderson have been the most prominent investigators of this phenomenon. They found that by injecting an animal with serum from another animal a hypersensitiveness was produced to the extent that a subsequent injection of the same serum, even in less quantity than first used, would result fatally to the animal.

The reaction was specific—that is, a rabbit injected first with serum from the horse was rendered sensitive only to horse serum, receiving with impunity, initial doses of serum from any other species of animal.

Further research proved that the reaction was due to the protein elements in the serum, no other principle causing anaphylaxis. Egg albumin was used with the identical result. It is possible to sensitize an animal to many kinds of protein at once, either by injecting them simultaneously or at different times. The initial dose is termed sensitizing, the second, intoxication. The period of time between these, or incubation period, is from 5 to 15

*Read before the Tri-County Medical Society, Bowling Green, April 9, 1912.

days, depending upon the animal's susceptibility more than size of dose.

Considering now the practical clinical features of anaphylaxis, we find that serum therapy is responsible for its place among the scientific facts of present day medicine.

At first any ill effects following the use of serums, were attributed to the anti-toxic bodies in them instead of to the serum itself. We speak especially of diphtheria antitoxin because it is representative of all the serums and too, is most universally employed.

Up to 1909 there were 22 recorded cases of sudden death following injections of diphtheria antitoxin.

Donaldson claims that we meet with some degree of anaphylaxis in about 20 per cent. of our patients but that 80 per cent of the serious cases are reinoculations rather than primary injections. It is a singular fact that asthmatics and individuals possessing a susceptibility to the odor of horses constitute practically all of the cases exhibiting intolerance to initial doses of diphtheria antitoxin.

SYMPTOMS OF ANAPHYLAXIS.

These vary from a mild urticaria to the most alarming manifestations, culminating in some instances, as has been stated, in sudden death. The respiratory centers seem to be especially involved, the heart continuing its action after respiration has ceased. The breathing simulates that of a severe asthmatic attack—may have rigors and convulsions or a state of coma ensue. Local symptoms are usually slight though sometimes have following quickly after an injection, widespread urticaria, edema and cyanosis of the face.

Treatment is principally prophylactic as anaphylaxis shock comes on so quickly we don't have much time to act.

The state of hypersusceptibility brought on by a sensitizing dose of antitoxin lasts ordinarily for two or three years, then gradually diminishes. It varies with individuals and amount used at original injection. So after three to five years we could, if necessary, safely reinoculate. Better still is to use an antitoxin the second time which has been derived from another species of animal.

Litterer uses in his immunizing work, antitoxin made by him from sheep and rabbit serum. Then any time subsequent to this the patient can receive safely a dose of the horse serum antitoxin.

For asthmatics and those who have been inoculated previously unless we can get a different kind of serum, the scratch test of Dr. August Calk is the logical procedure: Rub a small quantity of the anti-toxin into a scratch on the patient's arm—like the Von Pirquet tuberculin reaction—if there follows

a severe local or systemic reaction, its introduction into the body in full doses is contra-indicated. This is applicable only to immunizing work, where patient has been exposed. An active case we think should be given it, and the risk taken.

Netter recommends calcium lactate, grains 15, on day of injection and for two days following to prevent anaphylaxis symptoms and to relieve them when present. Litterer advocates trional and charcoal hydrate as preventives to the shock while he has gotten best results from hypodermics of atropine and adrenalin chloride as regards mitigating the shock once it is established.

A concentrated antitoxin should always be employed. Get less of the serum in this way and should also insist upon fresh antitoxin as the more concentrated loses its value quicker than that not so powerful.

Investigators the world over are attributing various diseases to forms of anaphylaxis. Among the more notable are pellagra, hay fever, mucous colitis, eczema and others.

We are all familiar with the luckless individual who at some time during his childhood becomes ill through partaking of, or over-indulgence in, some edible and can never eat of it again. H. N. Cole cites a particularly interesting case of a man aged 47 who became violently ill after eating buckwheat cakes. Dr. Cole vaccinated him with buckwheat flour using as a control, wheat flour. Within a few minutes he experienced a general depression; areas of edema and urticaria formed about the buckwheat injection, the other remaining absolutely normal.

From a practical viewpoint, we believe that a better understanding of anaphylaxis will be of great value in the artificial feeding of infants. Drs. Pisek and Pease in discussing the intolerance of milk by certain children and the resultant anaphylactic shock on their taking it, says: "It being impossible to sensitize an animal with its own proteins, a quick recovery would be expected if these children were placed on human milk which in fact is usually the only method by which they can be saved."

Grinnan points out the fact that many children do well on cow's milk for a week or ten days, the incubation period for serum sickness and after that time begin to have trouble.

We have all encountered instances where the babe would thrive on some one brand of infant food for ten days or two weeks, then not do so well until another had been substituted.

In conclusion will say that anaphylaxis is not responsible for all the ills of mankind, but we do believe that a more thorough realization of its possibilities together with a better

knowledge of measures to prevent and combat its harmful influences will result in the alleviation of much suffering and a saving of life.

ACUTE INTESTINAL OBSTRUCTION.*

By W. A. GUTHRIE, Franklin.

The causes of intestinal obstruction are various, and the obstruction may be complete or partial, acute or chronic. It may occur at any portion of the intestinal tract from the duodenum to the rectum. It may be either congenital or acquired.

But whatever may be the character of the obstruction, the one fact that predominates all considerations relative to treatment is, *it is a mechanical obstacle.*

A simple reference to the schedule of causes revealed by postmortem, establishes this fact and demonstrates as well the utter uselessness of medical measures.

In discussing acute intestinal obstruction it is necessary to take into consideration both the pathological anatomy and the clinical aspects of the subject and study the relations of one to the other.

What, then, has pathology taught us as to the causes of acute obstruction?

A careful collection of a large number of cases examined postmortem has shown that one of the five following causes is responsible with rare exceptions for acute obstruction.

1. Internal hernia.
2. Twists (volvulus).
3. Bands.
4. Intussusception.
5. Gallstones.

So constant is the relationship between acute cases and those causes that we can say with confidence that any given case is due to one of them.

In these cases the symptoms come on suddenly in a previously healthy individual, and are so strikingly characteristic that their significance can scarcely be overlooked by the well-informed practitioner.

The attack is sudden and acute. Pain is paroxysmal, central and fixed. Vomiting sets in early, first of the contents of the stomach, then of the duodenum, then of the small intestines. The patient becomes faint, pale, and markedly collapsed; constipation is absolute, not even flatus escaping from the bowels. Distention of the abdomen rapidly takes place, and distended coils of the intestine may often be seen and felt. The urine may be scanty and even suppressed.

It will be seen that these are the symptoms of acute strangulated hernia. There is the

same interruption of the onflow of the intestinal contents, the same obstruction to the blood current, the same disturbing and depressing effect upon the nervous system, the same violent peristaltic action in the endeavor to overcome the obstruction and push on the obstructed contents, the same paroxysmal pains, and eventually the same fatal result from precisely the same causes.

No doctor with the slightest conception of the true nature of the difficulty in acute strangulated hernia would think of overcoming it by giving purgatives, whose effect could only be disastrous, goading the intestines, already excited to their utmost, to increased and utterly useless peristalsis, aggravating the pains and suffering, and hastening the collapse which ends in death.

Nor could we expect, by the administration of opiates, in a case of strangulated hernia, to release the constricted intestine.

When, therefore, we are confronted with a case presenting such a group of symptoms, there can be no doubt as to the diagnosis. A dire disaster has befallen the patient. Death confronts him surely, and only the celerity, the courage, and the skill of the surgeon can rescue him from its grasp.

The bowels do not move. Shall we give purgatives? Already the bowel is making frantic efforts to force the blockade. Shall we stimulate it to more furious efforts to accomplish the impossible? No! A hundred times, no! It would be gross malpractice.

The patient suffers great pain. Shall we give opiates? If it is used only as an adjunct to annul pain, to relieve collapse, to restore the action of the kidneys; if it is administered for these purposes only, while the surgeon prepares to do his work, we may say, yes. If it is given with any curative purpose, then again No! emphatically, no! We but invite euthanasia. The patient, relieved of his suffering, is deluded with the idea that he is doing well. The doctor, no longer assailed by the cries of his patient, too often hesitates and delays, and the golden moments slip by during which the patient might be rescued from the otherwise inevitable doom. When the diagnosis is once made, every hour of delay is compromising the safety of the patient.

The bowel is damaged, peritonitis sets in, and collapse ensues, and the patient dies in spite of the delayed operation.

When the diagnosis of obstruction is made, coeliotomy is the only thing consistent with the diagnosis. If there is any doubt, an exploratory coeliotomy should be done to relieve that doubt.

It is scarcely worth while to discuss certain measures that are advised in these cases. If what use is irrigation or lavage of the stomach, except for putting the patient in better condi-

*Read before the Tri-County Medical Society, Franklin, July 9, 1912.

tion for the operation? Or distention of the colon with fluids, except for the same purpose? Tubage of the colon is a delusion, and manual exploration of the rectum a bit of brutal manipulation rarely justifiable. Taxis and nirsage, too, in my opinion, is useless.

Compression of the abdomen is a waste of time. None of these are curative and but serve to divert the attention from the one thing and only thing that can relieve the difficulty.

I am thus earnest in advocating early operation in these cases because I have seen them treated by the most powerful purgatives; by the administration of a quarter of a pound of liquid mercury, by delay extending over days, until the onset of peritonitis, the moist clammy skin, the hiccough, the stercoraceous vomiting, and the quickened pulse proclaimed any operation useless.

A few words must be said in this connection in regard to the differential diagnosis and treatment of acute intussusception. For, while it presents the usual symptoms of the obstruction of the bowels, there are certain symptoms peculiar to this condition.

By the term "intussusception" we mean inversion or prolapse of a portion of the bowel into the lumen of the part immediately adjoining. No portion of the intestines is exempt from this accident, though the relative frequency varies in different portions of the bowel.

In the inversion of the finger of a glove we have an exact representation of what takes place in intussusception, except that in the inversion of the bowel the mesentery is carried in with the intussusception.

The role played by the mesentery is important. As the invagination increases, the traction upon it increases, the tumor of which it forms a part is rendered somewhat crescentic, the pressure upon the lumen of the bowel is increased, and the facility of its reduction greatly interfered with.

The most frequent variety is the ileo-caecal, next the enteric, then the colic, while ileo-colic is the least frequent.

It is well to remember that intussusceptions occur in the dying. But as they give rise to no symptoms during life—indeed, are discovered only in post-mortem, they do not concern the surgeon. The absence of all indications of congestion or inflammatory action and the facility with which they can be reduced render diagnosis post-mortem easy. In intussusception the constipation is not so absolute except in very acute cases. A certain amount of diarrhea at the onset is frequent in a large proportion of cases, constipation becoming complete towards the close of the case.

In consequence of the great engorgement of

the invaginated portion of the bowel a certain amount of blood is found in the stools.

Tenesmus is a striking and usually an early symptom, and the occurrence of marked tenesmus with bloody mucous in connection with other symptoms of obstruction is almost pathognomonic. It is often mistaken for dysentery.

Vomiting is usually not so marked or distressing a symptom in intussusception. The presence of a tumor formed by the invaginated bowel can, in nearly fifty per cent. of the cases, be felt. It can more frequently be recognized in children than in adults, and is sometimes sausage shaped. It is most often to be felt over the transverse and descending colon. When it can be found it is a great aid in diagnosis.

As to treatment, I have succeeded in relieving quite a number of cases by distending the lower bowel with air or gas. I believe that an early resort to this method, before adhesions between the different layers of the peritoneum have taken place, will often be successful. Failing in this, an early resort to coeliotomy is demanded to reduce the invagination. This is much more readily accomplished before the great engorgement of the invaginated portion has taken place and peritonitis with adhesions of the peritoneal folds has set in.

The reduction of the invagination is best accomplished by a process of pushing the intussusception out from below while slight traction is made from above. A direct pull upon the invaginated portion of the bowel is apt to lead to tearing of the walls of the intestine, and the danger is greater the longer the invagination continues.

Obstruction in some of its forms is by no means infrequent, nor is the diagnosis always easy. In fact, judging from the injudicious treatment adopted in many cases, we must believe that the true condition is not recognized, or at least not appreciated in many cases. Post-mortem investigations have thrown a flood of light on these cases, and every well-poster practitioner should be familiar with their pathology.

While it is desirable to make a differential diagnosis as to the clinical cause in every case, it cannot be expected to do more than approximate the special cause in a given case. Nor should it influence the course to be pursued.

The suddenness with which appendicitis develops, the severity of the pain, the tendency to collapse, and the occasional vomiting might mislead the practitioner and lead to some confusion as to the diagnosis between obstruction and that disease. A consideration of a few points of difference may be of interest.

1st. Appendicitis is an inflammatory af-

fection. In obstruction inflammation is secondary.

2nd. Peritoneal irritation developed in appendicitis often causes great tenderness all over the abdomen; most marked over the region of the appendix, and later receding until it is limited to that region. Pressure over the abdomen in obstruction often adds to the comfort of the patient.

3d. The pain in appendicitis is more continuous and localized. In obstruction it is central and paroxysmal. Vomiting in appendicitis is by no means constant. In obstruction it is rarely absent.

In conclusion, I wish to make three positive statements in regard to acute intestinal obstruction.

1. Purgatives are absolutely not to be used in any case of acute obstruction.

2. The administration of opium as a remedial agent is to be strongly condemned.

3. Obstruction of the intestines is strictly surgical, and demand surgical measures for their relief.

DIETETICS IN TYPHOID FEVER.*

By D. G. SIMMONS, Adairville

The subject of dietetics is an important feature in the treatment of all diseases, and in none, perhaps, more than in typhoid fever. Indeed, until the cause of the disease shall have been more definitely established the proper selection and regulation of his food will naturally stand at the head of remedial agencies, to the end that his strength may be conserved and he be thus the better enabled to withstand the ravages of the long drawn out disease and reach the goal of health.

While I do not by any means wish to be regarded as a medical nihilist, which has recently been rather fashionable, especially among our respective friends of the scalpel, and while I fully recognize the necessity of drugs to meet the varying symptoms and conditions observed during the course of the disease, the use of drugs is only one of the remedies in the doctor's armamentarium, and judiciously used diet is another perhaps even more potent remedy in the successful management of typhoid fever. "A system of practice which assumes to substitute medicinal dynamics for the *vis medicatrix naturae* must be added to the list of bygone medical delusions."

There are two main purposes subserved by the use of food, viz.: First, to provide heat and energy, and, Second, to maintain a constant supply of new cells to supply the loss sustained by cell destruction going on in all

the tissues all the time, in sickness and in health. The continuance of life depends on the maintenance of both these functions. When heat fails, life is extinct, and when dead cells are not constantly removed and their place supplied by living cells, flesh and strength both melt away till death ends the scene.

The wonderfully ingenious and very interesting processes through which the food must pass in subserving these purposes of maintaining heat and renewing tissue are beside the question, and are not necessary to be considered in this connection.

There are certain classes of foods which are especially adapted to the production of heat and energy, and certain other classes are more especially adapted to the maintenance of tissue integrity. One of these functions is, as necessary as the other. Neither can be dispensed with. Hence a diversified diet is necessary. We must have heat and we must provide for tissue loss. In making selection of food to subservise both these functions, especially in typhoid fever, in which the powers of vitality are low, it is especially necessary to select those articles of diet which accomplish the purpose in view most effectually, and at the same time with as little irritation and as little tax on the digestive forces as possible. It may be urged that there is already too much heat in typhoid fever, but we must bear in mind that it is much better for the patient to obtain his heat from the proper use of carbohydrates than through tissue destruction, which is the only alternative if carbohydrates are not furnished.

The heat producing foods—the hydrocarbons and carbohydrates—are found in their best expression in starches—as found most commonly in bread, cereals, potatoes, rice, etc., also in fruits, fats, sugar and the various forms of alcohol.

The tissue forming foods—the albuminoids or proteids—are found most typically in meats, eggs, beans, cheese, etc. Some articles of diet contain more or less of both characteristics—both albuminoids and carbohydrates—one or the other feature usually predominating; such, for instance as milk, and bread made from the whole grains.

Out of the numerous articles found in these two classes of nutrients it is assigned to me to select such as are best suited to the requirements of the typhoid patient in his lame and lowered condition of vitality and organic function. The first and main purpose, of course, in making a selection is to give preference to those articles least irritating and most easily digested and assimilated; then the question of quantity and frequency of administration must be considered.

The consensus of opinion of the best med-

*Read before the Tri-County Medical Society, Bowling Green, Ky., April 9, 1912.

ical writers, as well as a personal bedside observation covering a period of fifty-two years, justifies me in the conclusion that pure, cool, sterilized milk in its various forms deservedly stands at the head of the diet list. It subserves the double purpose of furnishing both heat and tissue cells, and is the most easily digested of all food. It is the sole nourishment for the first period of infancy in animal life, and there is nothing that successfully takes the place of the mother's milk when her nursing children are sick. I am aware of the fact that for some years past there has arisen a prejudice against its use in this and other acute febrile diseases, but I am glad to see that the best and latest published authorities are endorsing its use, and have either never shared the prejudice against it, or are returning to its use. If sweet milk is used it should be fresh unskimmed milk, and to provide against the possibility of an excess of acid in the stomach or bowels, which would convert it into a cheesy mass, the milk should be mixed with about 10 per cent. of lime water, which doesn't alter its taste or nutritive properties. Personally, however, my preference would be buttermilk, the light organic acid in it usually imparting a refreshing taste to it. I once persuaded a young man with tuberculosis to use buttermilk. He said he didn't love it and never could drink it. He was induced to try it, however, and I am safe in saying he used barrels of it before his death. The adult should use from two to four pints during the twenty-four hours, giving it about every three hours. The alvine discharges should be inspected daily by the doctor, and if any curds are passing undigested then the quantity should be reduced, or if necessary, withdrawn for a while.

The patient should have plenty of cool, pure water. It is cool and refreshing, and favors the functional activity of all the organs of elimination.

The next most useful and innocent article of diet is uncooked egg—albumin. It is a pure albuminoid, is nearly always acceptable to the stomach, and entirely unirritating. It is best mixed with a pinch of salt, or a little orange or lemon juice, to overcome the fresh taste of it. The whole egg may be given in the later stages of the disease, either raw or soft-cooked. As a tissue builder it is unrivalled.

But in order not to disgust the patient's taste and wear him out on one unvarying bill of fare, it is necessary to vary the form of food or its method of administration. The milk and albumin may be combined, and if the patient should desire it, a little sugar may be added. The jellies are usually well relished, are well borne, and furnish a good force food. In place of using milk, continuously

day after day, with which the patient is likely to tire after a while, it may be alternated, day and day about, with meat broths, the meat well stewed down, and the broth slightly thickened with toasted crackers crumbled into it. The crackers should always be toasted. Sometimes a relish may be maintained for all the best adapted foods by alternating them every three hours. For instance, milk alternated with egg albumin, three hours from one to the other, or either one of them alternated with the meat broths. Milk toast may be given at breakfast by way of variety. A well relished and very nourishing combination, peculiarly well adapted to the period of convalescence, when the pulse is weak and the heart is feeble, is egg albumin mixed with unskimmed milk and about eight per cent. of good whiskey. This to be sweetened to suit the taste of the given patient.

The doctor is always importuned and frequently harrassed by the patient's constant demands, during convalescence, for more food and for unwholesome food, but the prudent doctor should remain firm and take no chances. Every doctor can recall one or more cases in which leniency proved disastrous. During convalescence a baked apple is admissible, and is nearly always well relished. The same may be said of stewed fruit if the fruit was well ripened before it was dried. Potatoes, baked with the skin on and just cooked enough to be mashed, thus allowing the steam to escape and leaving the potato dry and mealy, is one of the best of the force foods, and is well adapted to and well relished by convalescent patients. This list embraces a sufficient variety to cover the period of early convalescence, say two weeks after the temperature has decreased to normal. Great care should be observed to avoid returning to full feed too soon. I saw the importance of this in a recent epidemic of typhoid fever in and around my town, in which several patients suffered a relapse from over-eating too early in convalescence, thus prolonging their disease from one to several weeks.

THE IMPORTANT ETIOLOGIC FACTORS IN THE GASTRO-INTESTINAL DISEASES OF CHILDREN.*

By C. L. VENABLE, Franklin.

The study or theory of the causation of any disease is of the utmost importance to the physician. And when we begin to realize the toll of death each year from gastro-intestinal diseases of children it is indeed fearful. The importance of diarrhoeal diseases in children

*Read before the Tri-County Medical Society, Bowling Green, April 9, 1912.

can best be appreciated by reference to the following table, showing the mortality of these diseases in children under two years of age, as compared with that from certain infectious diseases for all ages. This table is for five years:

Total Deaths.	
Measles, all ages	3,378
Scarlet fever, all ages	4,152
Pertussis, all ages	2,000
Typhoid fever, all ages	3,523
Diphtheria, all ages	10,227
Total deaths from five diseases	23,330
Diarrheal diseases, under two years	26,563

There are several important underlying factors upon which diarrheal diseases depend. Their great frequency belongs to the first two years of life; after this time a notable diminution both in frequency and severity is seen, and a fatal outcome is relatively rare. The extreme susceptibility of infancy is due to several causes. The digestive organs are severely taxed to provide for the needs of the growing body. The mucous membranes of the gastro-enteric tract is very delicate in structure and has not much resistance; it is constantly exposed to injury by irritation and to infection. The next most striking fact about diarrheal diseases is their prevalence during the summer months, or season. This is graphically shown by the above table, the enormous increase in mortality does not have reference to any single form of diarrhea but to all forms.

While diarrheal diseases are especially frequent in cities and among the poor still they are not essentially diseases of the city or of poverty; severe, and even fatal cases, are met with among all classes and in all places. Diarrheal diseases are not essentially filth diseases; yet their frequency and severity are both increased by want of cleanliness in apartments and the persons and clothing of infants, especially the napkins, chiefly because these lead to a contamination of the food. Poverty and bad surroundings predispose to diarrhea in summer just as they do to other forms of acute disease in cold season. But more important still is the sort of care that the infant receives. Intelligent care even in very poor surroundings may enable children to escape serious diarrhea in summer. This result is due to not only the care of the person but includes intelligent management of feeding without which all methods are alike unsuccessful.

Anything which lowers the general vitality increases the liability to diarrheal diseases. Marasmus, malnutrition and rickets are especially important factors. There are cases in which diarrhea and dentition are closely as-

sociated, for the bowels quickly become normal when the teeth have pierced the gum. These cases although rare do occasionally occur. The infrequency of diarrhea during dentition in the cold season is the best argument against its importance as an etiological factor.

"Of all etiological factors the form of feeding is the most important. Of 1,943 cases which I have collected," says Holt, "only 3 per cent. had the breast exclusively." Fatal cases of diarrheal diseases in nursing infants are extremely rare. In most cases, however, it is not artificial feeding per se, but artificial feeding ignorantly and improperly done, which is to be blamed. If cow's milk is to be employed as a substitute for breast milk the difference in composition are either not appreciated or else ignored. So that many artificially-fed children suffer from malnutrition. The comparative safety of cow's milk in winter and in the country, however, shows that the chemical composition of cow's milk is not the most important factor. Another common and very serious mistake is that of over-feeding. Artificially-fed children are almost always overfed. The common practice of feeding an infant every time it cries, or of keeping the bottle at its mouth the better part of the time, is productive of untold harm.

The feeding of impure milk is an important cause of diarrheal diseases, especially among the poor of our cities, during the summer months. The different ways that milk can be contaminated are many. I am especially grateful to pure food laws for the strict enforcement of this, the greatest life-saving station that has ever been inaugurated in our country. Articles of food totally unsuited to the child's digestion are often given. It is a common practice among some seemingly intelligent families to give all kinds of solid food to children from 6 to 18 months old and those of two years the regular diet of the family.

The great majority of diarrheal cases can be traced directly to improper food, often to unripe or partly decayed fruit. The factors mentioned, over-feeding, too frequent feeding, and the habitual use of improper food, are probably the most important predisposing causes of diarrheal diseases.

As has been stated in this paper, age, general surroundings, constitution, food and method of feeding, and the hot season, the bacteria dysentery plays its part, although writers tell us there are other organisms that are just as important; one group being known as the "true shiga" or alkaline type, the other as the Flexner acid type. The latter has been found most frequently in this country.

BRONCHO-PNEUMONIA, CAPILLARY-BRONCHITIS, CATARRHAL-PNEUMONIA.*

By ROBERT T. HOCKER, Arlington.

Broncho-pneumonia, capillary-bronchitis, catarrhal-pneumonia is an inflammation of the small bronchi, and air vesicles due to the extension of the inflammation from the capillary bronchi to the air vesicles, or to inflammation set up atelectatic lobules.

The essential lesion is a productive inflammation of the bronchi and surrounding air spaces, productive in the sense of formation of new tissue. The disease prevails in a large percentage of cases among young children. It occurs in association with measles, scarlatina, diphtheria, influenza and pertussis, or as a sequela to them.

Many cases are entirely independent of them and may be appropriately classes as idiopathic. Infants are especially subject to the affection. Most cases of pneumonia occurring at this age are of this form. Lobar or croupous pneumonia being exceedingly rare in children under two years of age.

Many cases are traceable to improper exposure to cold, unsanitary surroundings, rickets or debilitated conditions.

The malady is common with the aged, attributable to debilitating diseases, emphysema, gout and weak heart action, from vulvular inflammation.

It occurs as a complication from typhoid fever, erysipelas and smallpox. When complicated, except in very mild cases, it is of serious import.

My own experience would indicate that while not uncommon with typhoid fever and occasionally with variola it rarely occurs with erysipelas, never having had a case of the kind in my work.

It is frequently caused by the tubercle bacillus. Bacteria streptococcus, diplococcus, pneumonococcus, staphylococcus and others are the formidable array against which we contend.

Primary broncho-pneumonia occurs in from thirty to thirty-five per cent. of all cases; is met with in most cases among children. The onset is unusually gradual in delicate subjects, suddenly, as a rule, in cases where previous health was good, cough from the start; expectoration mucopurulent, tenacious, sometimes tinged with droplets of blood; temperature ranges from 101 to 104 degrees in cases of moderate severity. In severe cases the fever is higher and continued. The majority of cases are of the secondary variety. Lobar pneumonia is liable to be overlooked, when

developed during the progress of other grave diseases. It is rarely ushered in with an initial chill, respirations are frequent; in young children may reach 60 to 80 per minute; pulse is frequent and liable to be weak and irregular in the latter stages. There is decided leukocytosis, a favorable condition, indicating good or fair resistance.

Percussion varies, sometimes nearly or quite normal, again dull or tympanitic.

Fatal cases usually terminate in two or three weeks; sometimes two or three days, suffices to close the scene. Cases terminating favorably are usually convalescent in from one to three weeks. Sometimes they continue six to eight weeks, when the onset is sudden the temperature high with convulsions, delirium alternating with stupor the pulmonary symptoms are likely to be overlooked. Other cases are of a sub-acute type and there is anorexia, nausea and vomiting. Generally broncho pneumonia develops suddenly. There is one or more chills, high fever, prostration, violent headache, pain in chest and loins, that in the loins being by far more severe than the chest pain.

The diagnosis is usually not difficult, the disease, for which it is most liable to be mistaken, is croupous pneumonia, the bronchial variety is usually secondary, to diseases already enumerated. The lobar form is usually a primary disease, expectoration, rust or prune-juice color; dullness greater, usually confined to one lung; definite duration, while symptoms of bronchial pneumonia, as already given, are almost totally different; is usually bilateral, expectoration much easier than in the croupous form. There are other points of difference but these will suffice.

PROGNOSIS.

The gravity of the disease is in ratio with the amount of lung tissue involved; many cases are so mild that they cause little or no anxiety, while the outlook is quite serious in others.

If the general condition is bad at the time of attack, an unfavorable termination is apt to occur.

Active children, thin in flesh, stand it better than fat ones. The death rate is higher in children in proportion to age. The younger have less chance for recovery. Mortality varies from twenty-five to fifty per cent. in secondary cases. In the primary form it is much lower, from ten to fifteen per cent.

TREATMENT.

Prophylaxis, by proper management in many cases, likely sixty-seven per cent., can be avoided. Giving close attention to the nose and mouth are important. Good warm clothing in cold weather.

*Read before the Carlisle County Medical Society.

The closest attention should be given in the convalescence of measles and pertussis, and guarding against contracting cold from protracted exposure. The sick room should be well ventilated, and an even temperature of about seventy degrees F., the air kept moist by steam from a kettle. Change of position in any lung trouble should be practiced. Local treatment during the first seven or more days: the linseed meal may be applied, changed at intervals of six hours, cover jacket with oiled silk; absorbant cotton may be substituted for jacket when improvement is marked. In older patients, ice may be applied for lowering the temperature and relief of nervousness. It has a good influence over local inflammation.

Tub baths are highly extolled for high fever, beginning with a temperature of 98, gradually lower to 80 or 75. In moderate fever cold sponging and the ice bag will suffice; in high temperature, veratrum is the most reliable and safest arterial sedative, and should be handled with proper care; tincture of aconite usually gives satisfactory results, antifebrine and phenacetin carefully administered are safe and efficient agents. At the outset, a mild calomel purge is indicated, later salines or glycerine suppositories are preferable. For cough a combination of syrup of wild cherry, syrup of squill compound, aromatic spirits of ammonia, sweet spirits of nitre and camphorated tincture of opium, ingredients varied according to indications, given every three, four or five hours, pro-nata will afford decided relief; whisky or brandy and strychnine are indicated if circulation is weak; only needed usually after the lapse of four or five days. Hoffman's anodyne is valuable for nausea, vomiting or difficult breathing.

Exhaustion of heart may occur suddenly with mucus rales in the large bronchi. Atropine in doses of from 1-150 to 1-200 may be given every second or third hour.

Alternating douches of hot and cold water may be used. Normal salt solution in indicated in increased arterial tension.

Electricity may be tried. In spontaneous cases the antistreptococci serum should be tried. Quinine to a child of two years, four to five grains per day divided into four or five doses at intervals of three to four hours, continued to the first and second stages, unless there is nausea. I am aware that I am occupying dangerous ground, but I have used this agent for over forty years without having cause to regret it. Many important points have not been noted, which I feel quite sure will be brought out in the discussion.

JAUNDICE.*

By A. P. DOWDEN, Eminence.

I thought I would ask your indulgence this afternoon in the discussion of a subject that we cannot term a disease, but like epilepsy, angina pectoris, asthma, etc., is only a symptom and we all know, too well, our patients can be ill or die from symptoms.

So I thought I would call your attention to the symptom met by all of us frequently, hoping that the discussion will bring out better methods of finding the cause and removing it.

I refer to jaundice, or icterus, a condition produced by the bile instead of being confined to its physiological receptacles, finds its way into the blood tissues and fluids of the body, staining them all a deep yellow. I believe all of the secretions contain bile, except the saliva and the secretions of mucous membranes.

Jaundice is divided into the two following classifications:

Hepatogenous—Due to obstruction, preventing escape of bile in natural way, the liver is performing its normal function.

Hematogenous—Observed in certain infectious diseases and certain conditions where poisonous materials finds its way into the blood.

Hepatogenous jaundice is very much like the condition causing dropsy, the free course of the blood is obstructed, the veins become over-distended, watery elements of the blood ooze out.

DIFFERENTIAL DIAGNOSIS.

Hepatogenous: (1) Always due to mechanical cause; (2) result of obstruction; (3) local affair; (4) yellow stain apt to be deep and excessive; (5) heart influenced, pulse slow; (6) temperature sub-normal; (7) evacuations white, foul odor; (8) itching.

Hematogenous: (1) blood origin; (2) staining slight; (3) pulse small, rapid; (4) tendency to hemorrhage; (5) elevated temperature; (6) feces dark, no evidence of the absence of bile.

ETIOLOGY.

Hepatogenous jaundice, inflammation, catarrh biliary passages, common bile duct or hepatic duct, causing closure of these ducts, catarrh of biliary canals in liver, parenchymatous inflammation, peri-hepatitis, duodenitis resulting in the inflammatory closure of the papillae where the common bile duct empties into the duodenum, causing the secretions to back into the liver.

Cirrhosis of the liver, cancer especially, if it involves the under surface of the liver, from pressure, tumors of the liver other than

*Read before the Henry County Medical Society.

malignant. Jaundice sometimes arises during the latter months of pregnancy, uterine and ovarian tumors, aneurism of the aorta and celiac axis, yellow, remittent or continued fever, gall stone colic if it lasts for some time, but it usually comes on after an attack due to inflammation, due to the irritation produced by the passage of the stone or by the impaction of the stone in the common duct, damage done by the stone in its passage causing an inflammation resulting in stricture of the duct, round worms by finding their way into the secretory ducts of the liver, blocking them up.

The symptoms of obstructive jaundice are urine highly colored, contains bile, yellow stain on skin and mucous membrane, linen stained from bile in perspiration, sight may be affected, patient seeing things yellow; bile found in blisters, occasionally in milk, pulse slow, full volume; if rapid, due to some inflammatory complication. Respiration, slow from the toxemia. Temperature sub-normal. nausea, vomiting, thirst, anorexia, pain and tenderness in the epigastrium, somnolence, headache, despondency, pruritis, constipation, sometimes followed by diarrhoea, an eliminating diarrhoea due to the decomposed matter acting as an irritant, nutrition below normal.

The nervous symptoms are coma and convulsions may occur if an organic lesion is present.

Duration depends upon cause, the disease may be considered at an end when we no longer find bile in the urine in great amount.

TREATMENT.

Like duration, treatment depends upon the cause. Don't give medicines to increase the action of the liver, find how the jaundice is produced, due in most cases to the catarrh of the biliary passages, if so give the liver rest, give remedies that attenuate and dilute the bile, in other words bleed the mucous membranes by salines, cathartics and diuretics, give medicines that will not increase the action of the liver but will increase the action of the mucous membranes, for instance, ipecac in small doses is an expectorant and diaphoretic, increase the secretion of the entire mucous membrane. We want remedies in obstructive jaundice that increase the secretions and at the same time dilute it, such as sodii phos., muriate of ammonia, salicylate of soda, podophyllin, mineral waters etc.

Electricity by use of the faradic current, one electrode over the gall bladder and the other over the spine at the same level, irrigation of the large bowel with cold water injections.

DIET.

Food that does not require the bile to facilitate its digestion, absorption or prevent its

decomposition, hence, skimmed milk, broths and egg albumen, fats and oils should be avoided.

As I have gone into the subject of obstructive jaundice deeper than I intended, I will not take up, this time, hematogenous jaundice or jaundice of the new-born.

REPORT OF CASE OF HYDROPHOBIA.*

By W. T. BRITT, Glasgow.

On June 10th, I was called to see a patient with Dr. Bullock. On arrival I found a nine-year-old girl in a strange condition, and she had been in that condition for three days and nights.

The history as Dr. Bullock gave it to me is as follows: She had been suffering from an intermitting malaria fever for three weeks, seeming some days to be better and then worse; complaining all the time of headache extending down in back of neck; also complained of her legs hurting her so she would have to lie down frequently through the day; appetite became poorer and poorer until she could not eat nor drink scarcely at all; constipated from the beginning, bowels had not moved but twice in three weeks in spite of all the doctor could do.

On Thursday, June 7, at 4 p. m., she was seized with what they called a spasm, which lasted her for some 20 to 40 minutes, then relaxed, but remained in that unconscious condition till just one hour earlier Friday p. m., when she was seized with another fit as the day before, which lasted 30 minutes or more, then relaxed partly; one side would be perfectly relaxed, the other rigid and would change from one side to the other, sometimes her arms would jerk over her head and sometimes only one arm would contract, each time seeming to try to work at her throat. Pupils widely dilated, no reaction, urine scanty, pulse 130, temperature 101 1-2, respiration 12 to 30, when rapid would blow froth through teeth; could not speak or move. Temperature never went above 102 1-2 degrees.

We watched her Saturday till after the regular time for these hard seizures to come on, but by this time she was so rigid and so completely overcome by the poison that she lay like a log, with breathing 6 to 20, pulse 150. I left at 7 o'clock not expecting she would live till morning. But if living the doctor was to telephone me. So he told me he could see no difference in her Sunday morning from Saturday night. So I told him I would come back and bring reports of the Pasteur Institute.

I did not reach the patient's house till 8

*Read before the Barren County Medical Society.

a. m. On arrival her mother told me she had missed her bad spell but had begun to have light spells every few minutes since early in the night before. Temperature 101 1-2 degrees, pulse 150, respiration 5 to 30; no sign of consciousness, could not take anything. Last medicine remained in her mouth for one hour and tablet was blown out as if it had not been in mouth.

Dr. Bullock and I watched her all day Sunday studying every symptom and comparing them with everything we had. We decided that beyond a doubt she was suffering from hydrophobia in the dumb variety, where paralysis comes on early and prevents one from that violent maniacal condition we sometimes see.

The girl was bitten in November, 1911, and while it seemed that the wound got well, her mother told me she had not been well since she was bitten. She was afraid to stay by herself, seemed to imagine she was not at home and had the peculiar hallucinations which characterize the first and second stages of that dread disease.

The patient remained in that semi-conscious and unconscious state from Thursday till Tuesday when she ceased to breathe and her spirit went to God who gave it.

This was a most horrible death which I hope I may never witness another like.

ERYSIPELAS; REPORT OF CASE.*

By W. W. RAY, Springfield.

It is my purpose in writing this paper to report a case which impresses me as having some features of unusual interest, and importance.

On the tenth day of August, 1911, I visited a ——— McElroy, a three-months-old girl baby, and found it with some fever, and an ugly phlegmon on the right lip of the vulva.

I predicted that this would be an abscess and would be ready for lancing in a few days. Instead of an abscess developing, the redness and tumefaction spread rapidly and soon involved the other labium, and extended up the body, and down the legs. Temperature was high, and pulse and respirations showed that there was profound constitutional involvement.

It was now apparent that the case was one of severe phlegmonous erysipelas.

The skin over the diseased area was tense, thickened, and of a coppery red. The symptoms of profound general infection soon became alarming. Pulse was very weak, and greatly accelerated, and temperature very high and persistent. Medical treatment gave meager if any results.

M. W. Hyatt was called in consultation. We gave 3000 units of antistreptococcus serum. No benefit: After about 18 hours, gave 4000 units still no effects, or slight if any.

The child was now very low indeed, and our spirits correspondingly low.

About this time we read a clinical report from some French or German physician who was claiming to have uniform success in the cure of all of his erysipelas by the use of the diphtheritic antitoxine.

It did not seem plausible to us. We know that the streptococcus was the germ found in most cases of erysipelas. No pathologist had, ever to our knowledge, found any of the Klebs-Loeffler bacilli in erysipelas. It did not seem rational or logical to inject antitoxine in our case, and yet: What to do? We were up against it! Alas, how often doctors are up against it. Out in the fog with only this little gleam of light to steer by; could it be a light-house gleaming in the distance, or only an ignis fatuus to bewilder us into deeper darkness? Well, we gave the antitoxine. Injected diphtheritic antitoxin for erysipelas. The results were as magical and marvelous, as we have all found them to be when this serum has been used in diphtheria.

In twelve hours it was plain that there was marked improvement all along the line.

In about thirty-six hours we repeated the dose when lo, the fight was practically over.

There were some small abscesses to be opened later and other non-essential details. But, the important point to this story is, that here was a case of erysipelas of unusual severity, promptly controlled by the administration of antitoxin.

Here is a matter of so much interest and importance that I feel that the sooner it is in the hands of the profession at large, so that they may consider the advisability of making further observations along this line, the better.

I know, of course, that results in a single case are not worth much except as they may serve to point the way; but I shall watch for further reports along this line with great interest.

Pre-Operative Nucleic Acid Has No Prophylactic Value.

—Preliminary injection of nucleic acid as a prophylaxis of peritonitis was given a thorough trial in von Eiselberg's service at Vienna but the conclusions are unfavorable. In 1,056 laparotomies done under the prophylactic injections the mortality from this cause was 4.6 per cent., but in a later series of 775 laparotomies, in which it was not used, the mortality averaged only 2.7 per cent.

*Read before the Washington County Medical Society.

NEWS ITEMS AND COMMENTS

LAUREL—Dr. H. S. Pitman, of East Bernstadt, has just returned from an extended visit to Texas.

MARSHALL—It is with regret we chronicle the death of Dr. L. E. Jones, of Benton, on July 3rd. Dr. Jones was in partnership with Dr. V. A. Stilley and enjoyed a large practice and the esteem of his many friends.

NELSON—Dr. B. E. Gore's charming daughter, Miss Margaret, was recently operated on for appendicitis and made a rapid and complete recovery very much to the gratification of her friends and the many friends of her father of whose eye she is the apple.

BARREN—Dr. A. B. Marcum, age 71, of Cave City, who was one of the oldest physicians in that town, died at his home, July 8th. About two weeks previous he received a small scratch, which developed septicemia; later an organic heart complication brought the end.

EDMONSON—Dr. A. T. McCormack, Prof. Wyckliffe Rose, of Washington, D. C., and Dr. W. L. Heizer filled an engagement at Brownsville and Bee Springs, giving an illustrated lecture on Hookworm and other preventable diseases. At both places, they were greeted with large and interesting audiences, and of the 150 specimens collected, a large per cent of them showed Hookworm infection. Arrangements were made to start a dispensary, a County Board of Health was organized and cooperation of many leading citizens was secured so that it seemed likely some real effective health work will be done in the near future.

Dr. W. S. Blakeman, of Glasgow Junction, died June 26th; by his death Barren County loses one of its leading physicians and the community one of its best citizens. His remains were carried to Walnut Hill Cemetery and given Masonic burial.

A special meeting of the Barren County Medical Society was held at the court house on July 9th; during the day Dr. H. N. Leavelle, an eminent physician of Louisville, held a clinic in the county court room for the examination and suggestion of treatment of all patients presented by physicians of the county. At night Dr. W. T. Boggess, a prominent physician of Louisville, delivered a free lecture on the subject, "A Health Talk to the Public." Dr. Boggess is a well known lecturer, and commanded a large and attentive audience.

FAYETTE—The Burley Tobacco Company has purchased the High Oaks Sanatorium property, to take possession as soon as Dr. George P. Sprague, who has conducted the sanatorium for many years, can complete his new sanatorium buildings on the property he has purchased about a half mile further out on the same street, South Broadway, Harrodsburg Pike. In the meantime, the Burley Society will build on part of the property which has not been used for sanatorium purposes, and will enter upon full possession as soon as the new sanatorium is ready to move into, which will probably be early next spring. The profession is to be congratulated that Dr. Sprague is going to erect this splendid new sanatorium.

COUNTY SOCIETY REPORTS

Ballard—The Ballard County Medical Society met with Dr. J. D. Rollings, at Hinkleville, on Tuesday, June 11, 1912. Members present: J. W. Meshew, H. V. Usher, Ezra Tilsworth, Bob Overby, B. F. Morris, W. A. Ashbrooks, Leslie Rudolph, C. E. Harkey, G. L. Thompson, J. S. Johnson. Meeting called to order by President Ezra Tilsworth. Minutes read and approved.

J. D. Rollings opened the program by making a talk on "Enterocolitis," which was discussed by the society.

H. B. Melton was absent, so his subject "Swat the Fly," was discussed by the society.

Ezra Tilsworth read a very interesting paper on "Therapeutic Value of Digitalis," which was enjoyed and discussed by the society.

After the meeting had adjourned the society was served with refreshments by Mrs. Rollings, which was enjoyed even more than the meeting. After voting this the most enjoyable meeting of the year, the society adjourned to meet on Fish Lake, near Barlow, July 16, in open meeting with McCracken County Medical Society.

J. S. JOHNSON, Secretary.

Carlisle—The Carlisle County Medical Society met at Cunningham, July 9, 1912, in the office of Dr. Shelbourne, Dr. Marshall in the chair. Members present: Drs. W. L. Mosby, Jackson, Marshall, Payne, Crouch, Shelbourne and Dunn.

W. L. Mosby read a very interesting paper on "Tuberculosis." The paper was well discussed by all present, and the discussion being closed by W. L. Mosby, after which the society adjourned for dinner.

Reassembled at 1:30 and program was continued, which consisted first of a paper by **W. Z. Jackson**, on "Patent Medicines." He gave an account of the ingredients and ill effects of Dr. King's New Discovery, Kilner's Swamp Root and several others, telling why they were detrimental to the people. The paper was discussed

by Mosby, Crouch, Marshall, Payne and, in closing by W. Z. Jackson.

G. W. Payne next read a paper on "Management and Prevention of Acute Contagious Diseases." He insists on vaccination, antitoxin, etc., and strict quarantine in all suspicious cases.

H. T. Crump's paper on "Management and Prevention of Bowel Troubles in Children," was quite entertaining as well as instructive. He gave the causes in such a plain manner that any mother could readily understand how to prevent the disease. A hearty discussion followed which was closed by the writer.

Motion made and carried to assess each member \$1.00 to meet incidentals.

A vote of thanks was tendered Mrs. Dr. Sheldbourne for the excellent dinner she had prepared.

On account of a misunderstanding the above papers were prepared for the benefit of the laity, but none were present. However, we all enjoyed the papers.

The society adjourned to meet the first Tuesday in September, at Fish Lake. The doctors are to take their families and have a nice outing.

J. F. DUNN, Secretary.

Fleming—The regular meeting of the Fleming County Medical Society was held in the office of Garr & Brice, Flemingsburg, Wednesday afternoon, June 19th, 1912.

Members present: Drs. Garr, Brice, Aitkin and O'annon. The meeting was called to order by the President, Chas. W. Aitkin. The minutes of the previous meeting were read and approved.

C. E. Garr reported a case of "Albuminuria." The patient had been rejected by an insurance company. The case brought up the subject of transient and permanent albuminuria in insurance risks. The discussion which followed was thorough and profitable.

There being no further business to come before the society, we adjourned to meet on the third Wednesday in July, 1912.

J. B. O'BANNON, Secretary.

Pendleton—The Pendleton County Medical Society met at the Day House, in Falmouth, on Wednesday, July 10th, 1912, with the following members present: Drs. Blackerby, Brown, Caldwell, Chipman, Clark, Daugherty, Ellis, Hopkins, Nickols, John E. Wilson, J. Ed Wilson, Woolery and W. H. Yelton. Drs. Givens and N. W. Moore, of Cynthiana, were present and added to the joys of the occasion.

After a few reports of clinical cases **Dr. Givens** gave us a splendid talk on the "Pupil in Health and Disease."

N. W. Moore read a paper on "Pellagra," which was ably discussed by some of our members, and by Dr. Givens also.

N. W. Moore then presented a case of "Typhus Vulgaris," that he had treated and cured with

the X-ray. Also a case in which he had not positively made the diagnosis yet but one he thinks is "Epithelioma."

Our society was delighted with having two such able members of the profession with us, and we certainly enjoyed their very able talks, Dr. Moore's able paper, and his presentation of the two clinical cases.

This was one of the most enjoyable meetings we have had.

W. A. McKENNEY, Secretary.

THE FORUM

FROM OUR BELOVED DR. STEELE BAILEY.

To the Editor:

To-morrow and to-morrow and to-morrow, creeps in this petty pace from day to day till the last syllable or recorded time, and all our yesterdays have lighted a great many clever people their way to Davy Jones' locker. So says the poet, but prophecy is a dangerous proposition, except to a favored few, in this vale of tears. Too many unsuspected factors are apt to arise to permit of certain judgments from the factors already known and determined.

My mentality warns me of my shortcomings; I comprehend that works adjourned have many stays and long demurs breed new delays. I have wanted a long time to return to my "first love," to throw my castor into the ring of the JOURNAL to say a word, (I haven't a thing worth distributing) but new delays have interposed. Knowing the generosity of the editor, and that he is not averse to pleasant words and kindly deeds, I venture a knock at the door, and here's a wish that it will be opened unto me.

I am in fine fettle and living backward now, to make a springtime of the winter which comes. The longing to stay young should be the doctor's delight; in this he is helping to make the soul immortal and to preserve youth—that is, if the desire is inspired by the right spirit, a hopeful spirit, and not a fretful longing. If a man is not an imbecile, he can always keep in a little cosy corner of his heart the feeling, or the fancy, that he is only twenty. He must caveat only a "little corner" as big plans do not balance small performances.

It is nice to be happy, to be where loud anthems are always ringing, to sit in complacent ease and eat whatever you want to and drink whatever you please—at twenty. But, we shall rest—and, faith we shall need it—when the last hip has been banished and the seams are all taken in. Dear, dear, if wishes were wings, good works would soon cease. Do you remember the story of Frankenstein?

The latter was a medical student, according to the authoress of that famous novelette. He conceived the idea of building a man and successfully did so. But unfortunately he builded a monster. It was one of the greatest stories of its day, though purely a mind-child. Now, in this day and generation, it is possible in reality that the old novel has proven prophetic. I observe that tissue of the human body removed immediately after death, bottled in chloride solutions and other media, and kept in cold storage, is now in demand in surgical operations. I thought it was a lot of Munchausenism when I read the statement made at Atlantic City that a section of "canned" cartilage was rushed from New York to Chicago by express for use in a case of knee disease. It arrived safely, was grafted into the knee, and the patient is now walking about the Windy City with a part of a dead man doing excellent service in his locomotive mechanism. Truly, the medical profession is to be ranked with the progressives. Yet, as a unit, I do not wish to make my quietus with a bare bodkin that some other one of the genus may play ball with my cartilages, and I shall try to prevent it, sure.

That reminds me: A very demure little French woman, who teachers her native tongue in a well-known college in the west, learned recently under embarrassing circumstances, that it is not always safe to accept as a final standard of correct English what she may casually hear.

One night at supper the president of the college announced to the assembled young ladies and teachers that an informal musical program would be given presently in the college chapel. Turning to the dainty Parisian, who, in addition to her other accomplishments, plays the piano well, he said:

"Perhaps Mme. Petit will be so good as to assist us."

The lady addressed arose and coyly replied: "I will do my durndest, professor," and I shall do likewise. I should think to dwell long upon "canned cartilage" in cold storage would induce delusions, or, at least, morbid introspections. Now, whether I should view the subject with Micawberish indifference—the so-called expectant treatment—is the question. To be serious; never before has the field of medical investigation been so extensive, the workers so many and able, and the methods of research so varied. Every generation of workers has had its special theories and supposed discoveries to test, to accept or discard. In no direction has the medical profession made greater advances in the last quarter of a century than in surgery. Give us facts, not fancies—proofs, not propositions, is the

demand of the medical mind of to-day. It is digested facts which nourish thought.

You may preach me a sermon on modesty and tell me that the shrinking violet is the noblest of emblems and the shy and retiring rabbit the model of human conduct; but as there is no anarchy in blowing the tops off of "schooners" I must insist on telling the illy-paid medical boys a novel way of successfully collecting long-delayed bills, which may be of value.

First, as I have a design under it, I will introduce the following, not that here is anything startling about it, but as being different from what we used to observe in the old commonwealth, in the lang syne. Every spring in this altitude of from seven to ten thousand feet, in the Titanic mining region, we see numbers of cases of acute lobar pneumonia. In severity it does not compare with the "Southern" variety. Whether the extremely dry atmosphere, the hyetometrography as an annual average recording not more than fifteen inches, the plentifulness of ozone, or the winds, and Æolus frequently does stunts of from forty to fifty miles, or the absence of germs, or what not, I shall not presume to divine; but the unvarnished fact is that nearly every case recovers; anyhow, there has been no mortality at his institution, nor in this canyon, from the malady recently. We throw physic to the canines and sieked 'em and with the exception of a weak solution of phosphoric acid no other medicament was employed. The disease would have terminated abruptly and naturally without a dose of physic. Even the customary pneumonia-jacket was omitted. The adynamia of the disease is due to a systemic poisoning and not to exhaustion; therefore, overfeeding was deprecated—a heavy diet is liable to intensify the already labored respiration. After consolidation has taken place, hyperpyrexia was treated by alcohol sponges with friction and an ice bag to the head and heart, but no internal antipyretics. There are tricks in all trades except ours. There is no sleight of hand in curing every case, if the attendant will not be "fussy" nor afraid to carry out his convictions. I know, because it is his duty, that the doctor will not neglect the luxury of his daily calls. No angel bands will follow him and there is a reasonable hope of bread and butter behind the patients. One of the attractions of a practitioner in a quartz mining camp is, that he suffers not the anguish and despair in the collection of his I. O. U's, which beset the medical man, especially, in some parts of the country. The doctor is glorified, magnified as he was in the days of the Bonnie Brier Bush, or in the early settlement of Kentucky, when ministers of grace, as well as those of the body, were a rarity. The mines pay on

the first of the month and all honest miners endeavor to remember the doctor with either much or little, soon thereafter. There is no denying the fact that the medico is beaten occasionally and to make assurance doubly sure he is forced, on occasion, to resort to strategy.

A story is told of one of my medical friends in Tonah, which shows there are divers methods of collecting bills. Several months ago a well known Tonah lady engaged a cook, but the pay days were postponed and instead of coin of the realm being paid for the services only promises resulted. One morning the lady of the house arose and on visiting the breakfast room was astonished to find that no preparations had been made for the morning meal. She hastily went to the hired girl's bedroom, where the servant was found in bed and who complained of being ill. The doctor was summoned and after making an examination asked the girl if she were really sick. There was no response to the interrogation, except a mute look of appeal from the patient. The mistress left the room at this time and the girl blurted out:

"No, I am not sick, only the lady owes me three months' wages and I am going to stay in this bed until I receive my pay."

"Well, as Paddy said in the fight, 'for God's sake somebody hold me,'" replied the M. D. "Move over, give me room and I'll stay too, she owes me one hundred dollars."

I have come to the end of my tether. However, I could become more prolix and tiresome if I had a mind to. My readers may be impressed with the same idea I have of this epistle; that it is an exceedingly funny thing why some well-meaning folk have the ability, while others of equally strong mental calibre do not possess it, of writing all they know on a postage stamp and without cancelling the stamp. Sure, they must carry a little penny in the pocket, with a hole in it, for good luck.

My best wishes for the health and prosperity of the Association and love to you and yours, I am

Verily and inviolably,

STEELE BAILEY.

Mammoth City, Utah, July 3, 1912.

Primary Ethyl Chlorid Anesthesia.—Stieda and Zander have done over a thousand minor operations during the last year under anesthesia induced by the first whiffs of ethyl chlorid. They commend it as a convenient and effectual mode of anesthetizing for a brief operation. The operator must resist the tendency to give more of the ethyl chlorid than is necessary; the fact that the patient retains his consciousness is misleading in this respect. From 20 to 40 drops suffice for women and children; men may require up to twice this.

Differentiation of Hydronephrosis.—Trinkler reports a case of assumed hydronephrosis. Cystoscopy showed that he right ureter gave less urine than the left which seemed to be working normally. The tumor was spherical; it had developed in less than two days and its location in the rear of the hypochondrium and front of the lumbar region, and the transmission of fluctuation up into the right kidney region on percussion from the front—all signs pointed to right hydronephrosis; gynecologists consulted said that the genital apparatus was not involved. The tumor proved to be an ovarian cyst with a very long pedicle which had become twisted. Adhesions between the cyst and the liver kept the cyst unusually high. When the liver is enlarged and congested, it is liable to push the kidney down and fill its place. In another case recently the liver and gall-bladder had sagged into the lumbar region while the kidney had been pushed over toward the bifurcation of the aorta, almost into the small pelvis. In the two cases previously mentioned the cystoscopic findings were misleading; the reduced output from the right kidney was not due to functional but to mechanical causes.

Ascending Currents in Mucous Canals and Ducts.—Goldmann introduced into the rectum a capsule containing charcoal or indigo in a number of patients with a fistula in the bowel, and in from one to three days particles of the foreign substance appeared in the fistula, proving the existence of antiperistaltic movements or retrograde transportation of the particles. He obtained positive findings also in experimental work and in cases of fistulas in to the bile apparatus when the foreign substances were given by the mouth. Everything tends to show that retrograde transportation of bacteria and minute foreign bodies may be responsible for infection or may supply the nucleus for a concrement. The same factors may aid in the production of concrement in the urinary passages, salivary glands and appendix. Stagnation in canals and ducts favors this retrograde ascending current and subsequent infection, and hence should be combatted early.

Differential Diagnosis of Cancer and Simple Achylia.—Einstein has been studying the amount of dissolved albumin in the stomach content which Wolff and Junghaus assert are characteristic for cancer. (Their statements were summarized in *The Journal A. M. A.*, July 8, 1911, p. 172). They found in malignant diseases a large proportion of dissolved albumin in the stomach content one hour after the test meal with a very small proportion of pepsin and hydrochloric acid. Einstein's research confirms the importance of this test, the findings serving to differentiate simple achylia from the aepsia with malignant disease.

FRACTURES OF THE SKULL.

By J. GARLAND SHERRILL, Louisville.

My decision to present this subject for your consideration was formed because of six cases of actual, and one of suspected fracture of the skull which came under my observation in the last few months. All of these save one were in private practice, and each in itself of some interest and to me at least the cases were quite instructive.

CASE I.

H. M., was hit over the head with a six-pound hammer. When I saw him his attendants had already incised the scalp, upon which there were three wounds, one on the right side near the occiput; another on the right side of the forehead, and one near the median line in the forehead, such as might be caused by the hammer described. He also had a wound on the right side of the lower jaw, with fracture. Almost the entire right side of the skull was shattered; the right hemisphere of the brain pulplified, and fluctuant, and considerable brain tissue escaped from the posterior wound.

The fragments were lifted from the brain, the fracture evidently leading to the base. Considerable hemorrhage occurred from the right ear. The patient's pulse became somewhat weak upon the table and he received a litre of saline solution. He left the table with a pulse of fair volume—about 80; partially regained consciousness, but lapsed into coma and died at eleven o'clock the next day, the tension of the pulse being fair until the end.

CASE II.

C., white, male, 58 years of age. Was struck on the right side of the back of the head with an iron pipe, making a wound about three inches in length. He also had another blow on the forehead, making a wound about one inch in length. His left cheek showed evidence of a brush burn, and there was a bruise upon his nose, probably where he fell.

DIAGNOSIS.

A compound fracture of the vault of the skull. Under chloroform anesthesia the wounds were enlarged and in the anterior one a double linear fracture was found, with a depression about one inch across and two and one-half inches long. This was elevated and the line of fracture chiseled out for drainage. The patient's convalescence was uninterrupted.

CASE III.

T. D., white, male, age 54 years. Excessive user of alcohol. Was found on the street unconscious. Brought to the hospital January 6th. On examination the patient was bleeding from the left ear, profoundly unconscious; pupils unequal; pulse slow and full; stertorous breathing, but temperature normal. Slight wound over the left eye. Patient was seen in my absence by Dr. McCoy.

DIAGNOSIS.

Fracture of the base of the skull; wound over the eye was sutured; the ear was cleansed and packed.

TREATMENT.

Rest and elimination.

Patient made a gradual but complete recovery. Discharged two weeks later in first rate condition.

CASE IV.

Mr. L., white, aged 45 years. Was injured by a blow over the left mastoid process, fracturing and crushing that portion of the temporal bone; accompanying it was a hemorrhage from the left ear; temporarily unconscious, followed by mental sluggishness and irritability. I saw him twenty-four hours later and advised quiet and the use of an ice cap, purgatives and the bromide of sodium. The patient improved gradually, but somewhat slowly.

CASE V.

J. B., white, male, aged 61 years. History of having fallen into a cistern, striking his head. There was a small scalp wound at the back of the head and a small hematoma in the right temple; hemorrhage from the right ear. Patient was immediately unconscious, the pupils not responsive to light. Later he vomited and showed slight improvement. Saw him about twelve hours after his injury, with the following conditions present:

Pupils contracted and responding to light, but sluggish; muscular power good, no paralysis; sensation good. He could be aroused, but was apparently unable to hear, and outside of one or two words was not able to speak. Temperature 98 1-2 in one axilla and 99 in the other; pulse rate 60.

DIAGNOSIS.

Fracture of the base of the skull with slight cerebral contusion. Owing to lack of focal symptoms and the slight improvement shown in his condition the plan of expectancy was advised. The patient made a very gradual but complete recovery.

CASE VI.

G. G., white, aged 11 years, male. This boy was injured by an automobile, two days prior to my first visit. His right arm and leg were abraded. A large hematoma on the scalp, with evidence of depressed bone; cracked-pot note on percussion. His pupils were normal and responded to light; pulse was somewhat rapid; intelligence was clear, but he complained of headache.

DIAGNOSIS.

Fracture of the skull with depression. Operation upon the following day. A seven inch incision was made over the left side of the skull, revealing a long linear fracture with a stellate depression at its anterior end. The depressed fragments were in part removed and in part elevated and the linear fracture widened for examination. Patient left the table in good condition. Complained of some headache during the first night, but this soon subsided and he made a good recovery. Left the hospital on the eleventh day.

CASE VII.

C. L., male, white, aged 5 years. He was found unconscious in the street, apparently having fallen off the rear of a wagon. His attendant had made diagnosis of fracture of the skull, based upon unconsciousness, unequal pupils, and full strong pulse. I saw him twenty-four hours after the injury. At my examination there was no evidence of skull fracture; no evidence of injury to the brain, and patient in very fair condition. Advised non-interference. The patient left the hospital the second day and made a perfect recovery.

Much discussion has developed over the various methods by which fracture of the skull may occur. Such violence has been described as direct and indirect, the term "direct" being applied to such violence as is followed by fracture at the point of impact, as in an incised fracture from a sharp instrument; while that producing a fracture at a distance from this point has been called "indirect," as in cases of fracture from contre-coup, or from falls on the feet. As a matter of fact violence in every case must be applied to the skull itself for a fracture to occur, although the force of the blow may be expended at a distance from the point of application. Fracture, therefore, may occur at a point opposite to the blow, as in the case of a bursting fracture, or may be equi-distant from the point of impact and the point of resistance. An example of this form of fracture is shown in the bursting fracture resulting when a nut is compressed in a nut-cracker. A similar form of injury is seen when the head is thrown forcibly against a hard object. There is here what the French call *tassement*, or piling up of violence. In such cases the violence is of necessity great, the line of fracture extensive even in the absence of much contusion. On the other hand the resultant fracture from a direct blow depends upon the weight, force, and size of the wounding object. In the first group there is likely to be produced a diffused contusion or laceration of brain substance with the usual symptoms of shock, concussion or contusion of the brain, the lines of fracture often leading to the base of the skull; yet in many cases there is no injury of large vessels or bleeding at the point of impact, and rarely pressure of the fragment of bone upon the brain is present. A number of years ago I saw a case of this kind with Dr. Speidel, where a child had fallen from a second story striking its head upon the pavement. The bones were crushed for some considerable distance but caused no pressure upon the brain, nor was there any distinct hematoma present, yet the damage done to the brain tissue was so great that death followed very promptly.

In the other class of cases, produced by a blunt object, the injury to the bone may be quite localized, producing an open wound with a depression of a limited amount of bone, which in one instance may result immediately or shortly in death of the patient, or in another may cause but little disturbance. An example of the first is seen in the killing of calves and sheep in the abattoir.

A number of years ago I saw a visiting athlete who was hit with a twelve pound hammer in the center of the forehead, causing marked depression and considerable destruction of the brain tissue, producing complete paralysis; unconsciousness; loss of reflexes and slow stertorous respiration, with a very slow pulse of excessively high tension. This patient died from respiratory paralysis during efforts to lift the fragments of bone from the brain.

In another instance the bone may be shattered into many small pieces with but slight injury to the brain, the patient remaining conscious and fairly comfortable throughout. It may be well to state at this point that a very serious intra-cranial lesion may occur without evidence of injury to the scalp, and again rupture of a meningeal vessel may occur, as well as considerable damage to the brain without a break in the outer table of the skull. This is the result of the elasticity of the skull, which is forced inward by the blow, pressing upon the brain and returning without producing fracture. Felizet and others have thoroughly demonstrated this point. Von Bruns has shown that by placing a skull in a vise and compressing it that its diameter was materially reduced before fracture occurred, a diminution of from five to ten millimeters being often observed.

The symptoms in a given case will depend upon the location of the fracture, whether of vault or base and its extent; and upon the injury to the delicate structures within the skull. Symptoms indicative of a fracture are very frequently delayed for some time after the occurrence of the injury. I recall two cases terminating fatally in which symptoms of serious injury of the brain were not present for over twelve hours. In each of these cases the fracture extended from the vault to the base, and one almost entirely across the base of the skull.

DIAGNOSIS.

Fractures of the vault can be made out with more certainty in the larger number of cases than those of the base, the symptoms in the latter being less direct. Compound fractures of the vault are especially easy of diagnosis, because of actual sight and feel of the line of fracture. The test so universally given to tell the line of fracture from that of

a fissure or of a Wormian bone is classic. The cases which are difficult to make out are the simple linear fractures without depression. A line of tenderness to pressure not explained by contusion to the soft parts is a valuable sign. If upon percussion there can be elicited a cracked-pot note, fracture is certain. A skiagraph will oftentimes show a line of fracture in the vault, but frequently fails in case the fracture is at the base.

The diagnosis of basal fractures will be made by (a) the kind and direction of the violence; (b) by the signs of hemorrhage from the broken bone; (c) by the escape of cranial contents, and (d) by symptoms due to lesions of the cranial nerves.

If the fracture is in the posterior fossa, hemorrhage often appears two or three days later at the tip of the mastoid; if in the middle fossa, hemorrhage will occur from the ear and perhaps from the throat. If fractures of the anterior fossa, bleeding from the nose or into the orbit is strongly suggestive of the injury. Hemorrhage resulting from fractures of the orbital plate, according to Rawlings, appears at the outer canthus and progresses inward to the corneo-scleral margin.

On the other hand palpebral hemorrhage from a superficial blow with fracture begins on the inner side and progresses into the tissues of the upper and lower lids. Exophthalmos may occur if blood is poured out behind the bulbus oculi. It is always slight if the smaller vessels are torn; if the orbital branches of the middle meningeal or if the cavernous sinus is torn the proptosis is marked. Rawlings, quoted by Archibald, tabulates this condition in three groups:

1st. Proptosis, occurring almost at once, severe and progressive; fracture in sphenoidal fissure or cavernous sinus probable, with extravasation of blood forward; thrombosis of the sinus or damage to the internal carotid may co-exist.

2nd. Proptosis, moderate, and appearing after a few hours will indicate a fracture of the orbital wall; rupture of the ophthalmic vessels.

3rd. Proptosis, appearing days or weeks after the injury, usually steadily progressive. One can diagnose here a fracture near the cavernous sinus with arterio-venous aneurism.

TREATMENT.

There is perhaps no class of injuries which demand a higher degree of surgical judgment in their management than do fractures of the skull. While it is a fact that prompt and early interference when indicated will give the lowest mortality and best permanent results, it is nevertheless true that a very considerable amount of judgment is necessary to tell which case demands prompt operation and

which would do the best under expectant treatment. I am positive that in my early enthusiasm I have erred in operating upon cases where my present knowledge would forbid such a step. On the contrary the surgeon should not by procrastination and delay or because of timidity allow a patient to die from pressure due to intra-cranial hemorrhage, or from meningitis following a compound fracture without interference. This was forcibly impressed upon me a number of years ago in a case of suspected fracture of the base which I saw with Dr. Phillips. The patient had an injury to the head and presented but few symptoms, so that when I saw him about three days later I advised that Dr. Phillips continue the expectant treatment he was then employing, with the result that the patient developed meningitis and died, the infection probably having occurred through a break in the pharynx. It is doubtful if any hard and fast rules can be laid down upon which one can base a plan of treatment. This is largely due to the fact that the symptoms vary so greatly in the different cases. All observers are agreed that compound fractures of the skull, even without brain symptoms, should be trephined to prevent possibility of infection and meningitis. Access in these cases is easy, and in the severe cases with evidences of pressure the operation may be done with little or no anesthetic. In depressed fractures operation is advised to prevent the later nervous troubles so prone to follow. The interference in this class of cases need not be done hurriedly except with pressure symptoms, although it is unwise to delay too long lest the epilepsy or persistent headache be already determined. Linear fractures without depression or brain symptoms should not be opened, although some writers do not agree with this advice, claiming the subsequent history is better when they have been explored. Linear fractures with brain symptoms should be submitted to operation unless it is clear that operation is contraindicated. Gunshot fractures should be explored and the bullet, if possible, removed. Just here a word of caution may well be inserted, viz., the delicate brain tissue should be disturbed as little as possible, for although at times one remarks how much damage it can withstand, still the insult should be limited to a minimum amount.

In fractures of the base of compound type all possible sources of infection must be rendered sterile if possible; ears with rupture of the drum and escape of cerebral fluid should be gently cleansed by small pieces of sterile gauze or cotton and lightly packed with gauze. Alcohol is a splendid cleansing agent. The blood and meningeal fluid are sterile and wash out some infection. Peroxide of hydro-

gen should be not used because it may force bacteria into the minute crack or fissure in the skull. Powders, too, are to be avoided. The nose, throat and mouth should be cleansed with saline solution, even if there be no evidence of lesion in the nose or pharynx. Upon the appearance of meningitis drainage of the fossae of the base is indicated, although often of no avail.

The prognosis in a given case will depend very largely upon the symptoms, some remarkable recoveries occurring, while other apparently trivial injuries result in death. The cases which I dread to see are the very serious bursting fractures caused by falls from a height or in similar manner with unconsciousness, prostration, pallor, fast feeble pulse, and cold clammy sweat; pupils responding but feebly to light, or perhaps not at all; respiration feeble and shallow. Special senses abolished, with or without paralysis, but showing no tendency to rally or to restoration of consciousness. I take these symptoms to mean a marked contusion of brain tissue, many minute lacerations of structure and small hemorrhage. In my experience these cases die, especially in children—and die more promptly if subjected to immediate operation. If they have a chance it is after time has been allowed for a restoration in part at least of the cerebral equilibrium. Marked bone depression with great laceration of brain tissue and a very slow pulse of high tense, very slow and stertorous respiration, complete paralysis and total loss of consciousness makes a very grave prognosis, and the gravity is increased if the pulse becomes suddenly very rapid, showing exhaustion of the circulatory apparatus. Some of these cases, however, with much hemorrhage often show brilliant results following prompt trephining.

In operating upon such a case care must be employed to lift the fragments with as little displacement as possible, lest a vital part be pressed upon with sudden cessation of respiration. Artificial respiration becomes a valuable aid at this juncture.

The cases most hopeful are those not completely unconscious with a pulse not below 60, of good volume but not too high tension, with no paralysis or a limited loss of power in certain localized groups of muscle—with or without evidence of extra dural hemorrhage, provided prompt operative interference is employed.

In making an operation certain points must not be overlooked:

- 1st. Rapid work.
- 2nd. Minimum loss of blood. Patients, especially children, can stand the loss of a smaller amount of blood from the interior of the skull than any other part of the body.

Cerebral anemia and great shock are to be expected, therefore hemorrhage is to be prevented in every way possible. Use minimum amount of anesthetic commensurate with complete relaxation. While I have and do use chisels at times, I have always thought the danger of jarring to be by no means a small one and avoid it as much as possible.

DISCUSSION.

Irvin Abell: Unfortunately, this excellent paper has been presented at such a late hour and the subject is such a tremendous one that, while I think a full discussion would be interesting, I shall limit my remarks to fractures of the base.

The indication in fracture of the vortex of the skull is, as Dr. Sherrill has stated, very plain. In fracture of the base the question of operation or the expectant plan of treatment is one that, for me, has always been very difficult of decision. In cases that are immediately unconscious and present no focal symptoms, I do not see how it is possible to make a diagnosis of either the location or probable extension of the fracture. A perusal of the literature on the subject would indicate that the majority of operators of largest experience prefer to do decompression operations in all cases of fracture of the skull attended by coma. In my own personal experience, I have not been, and am not yet, able to determine whether decompression is of any great value in these cases, since, as brought out in Dr. Sherrill's report, many of them recover without decompression. Therefore, except in those cases where there is a distinct haematoma, either intradural or subdural, I have been unable to decide, to my own satisfaction at least, that decompression has been of any service. The old rule in these cases was to await the onset of definite evidence of compression, which is practically always due to hemorrhage. If due to oedema of the brain, depression will, as a rule, do no good. In those cases where we are able to find a distinct haematoma (and unless focal symptoms are present it is impossible to say in which region of the brain such clot exists), decompression is usually done through the sub-temporal fossa.

Still another type of cases is that in which there is no coma; in which there is high temperature, sometimes going to 104 or 105 within the course of three or four hours following the injury; in which there is delirium; the pulse instead of low, is high; there are practically no pupil signs and no focal symptoms. I have such a case at present that is getting well without decompression. On the contrary, I have done decompression in such cases and they have recovered. Therefore, I do not know whether or not decompression does any good in these cases.

Possibly Dr. Sherrill will recall a symposium on this subject at the meeting of the American Medical Association, two years ago, in which the

most diverse opinions were expressed in regard to whether or not decompression was of any value in fractures of the base where there is no distinct indication for decompression in the shape of focal lesions.

W. C. Dugan: The question of the diagnosis of basilar fracture is very interesting. One point that I would like to call attention to is spinal puncture, which the essayist did not mention, but which I think is very valuable in making diagnosis of fracture of the base. If we find hemorrhage, we can feel pretty certain of the existence of a fracture. In fracture of the posterior fossa, palpation of the posterior pharyngeal wall is valuable, because there is always extravasation of the cerebro-spinal fluid at this point.

Hemorrhage from the ear is one of the most misleading of symptoms. I have seen a number of cases in which diagnosis of fracture had been made, but upon examining the patient and going carefully into the history, it proved to be nothing more than hemorrhage from ulceration of the membrane. Such hemorrhage is of short duration and almost always arterial, while hemorrhage from the ear in basilar fracture is persistent and venous, and there is always a considerable quantity. We may have a fracture of the base, through the middle fossa, without the extravasation of cerebrospinal fluid, but it is invariably present when we have a fracture going through the petrous portion of the temporal bone and tapping the sheath of the nerve. There we have a large amount of fluid. Sometimes we have a fluid very much like it, coming from the cells, that is sometimes diagnosed cerebrospinal fluid, but it is not present in such quantities as when we find the cerebrospinal fluid.

I agree with Dr. Abell in regard to operation in these cases. Not long ago I was called to see a patient who had been unconscious from the time she had been thrown violently from her buggy against a tree. I saw her several days afterwards, and refused to do anything in the way of operation, advising purgation and the application of cold to the head. I firmly believe that patient would have died on the table. I do not mean to imply that I weighed my reputation against the patient's life, but I do not believe operation would have given the patient any chance. In a case of that kind, where there are no focal symptoms, and nothing to indicate where to attack the condition, I think it is best to leave them alone. In such a case there may be no fracture of the skull. It has frequently been demonstrated that the brain may be absolutely pulsified by striking the head with a sandbag, or even a solid instrument, without fracturing the skull. Again, we may have a fracture of the inner table, which is very brittle and easily broken.

When I am called to see a patient that has been unconscious since the injury was received, where I find evidence of depressed bone and the patient

is in profound shock, and where the symptoms of concussion are not predominating, I will operate, with the understanding that the chances are the patient will die. I have seen a great many cases, and I can recall but one patient, unconscious from the time of the accident, that recovered. They do not die from hemorrhage, but simply from injury to the brain. I believe that in nearly all of these cases the unconsciousness is due to laceration of the brain tissue. If nature is able to cope with it, the patient will recover, but their recovery will be very slow.

I recall the case of a man who was kicked out of a saloon one Sunday night after being struck on the head with a beer glass. He finally got up and went home, and the next morning he had a "Monday headache" and did not go to work. He worked Tuesday, Wednesday and Thursday, came home cross and slapped the children around and abused his wife. On Friday he complained of headache and slept a good deal. Saturday morning he did not get up, and on Saturday evening his brother came in from the country and found him in a sort of stupor. On Sunday night the brother asked me to come and see him, but I told him it was entirely useless; that his brother had a fracture of the skull with hemorrhage, and to take him to the Infirmary at once. He was operated upon and a large hemorrhage found.

These cases are all the same; the symptoms are either due to hemorrhage or to pressure upon the brain as the result of depressed bone.

In regard to the prognosis, I want to state again that, in fracture of the vault, where the patient is conscious immediately after the injury and later lapses into unconsciousness, if you see him early enough, you may be able to save him; but where the patient is unconscious from the time of the injury, and does not react after a reasonable length of time, they will practically all die. If any such cases recover it will only be after a very long and tedious convalescence.

A. David Willmoth: This is a most excellent and interesting paper, and I think the majority of us are in accord with the most important points that have been covered by the essayist and the other speakers.

The point brought out by Dr. Dugan, about puncture of the spinal cord, is a most excellent one for two reasons. It enables us to tell, not only whether there is a fracture of the base of the skull, but also whether it extends through the bone and soft structures into the ventricle. There is just one danger; that is, the jamming down of the base of the brain into the base of the skull, or into the foramen magnum. This can be obviated if, at the time the puncture is made, we will force back into the canal the fluid that has been withdrawn for diagnostic purposes. This is done on first evidence of dangerous symptoms and before syringe is withdrawn.

I agree with Dr. Dugan in regard to fractures

of the vault. Those that go along with the so-called free interval with focal symptoms of a local lesion, are all amenable to surgical treatment, and, with very few exceptions, get well. On the other hand, those that are unconscious from the beginning, indicating that we have laceration of the brain substance instead of hemorrhage to contend with, will almost every one die.

This brings me to the point brought out by Dr. Abell. He stated that he has a case, in which there was a rapid rise of temperature to above 104 degrees F., that is recovering. Those of you who are familiar with the work that Phelps has done along this line will remember the table laid down by him, showing that those cases with a primary temperature above 103 will practically all die, and those with a secondary temperature above 105 will practically all die. It is interesting to know that Dr. Abell's patient, with a primary temperature of 105, is recovering. This would seem to be an exception to the rule laid down by Phelps.

In fractures of the base not attended by focal symptoms, sometimes the escape of blood from the ears or from any part of the body, will relieve the pressure on the brain; or, if there is free escape of cerebrospinal fluid, the same end will be accomplished.

I think Dr. Abell's remarks are well taken, and his views should be of value insofar as the operation of decompression is concerned. At the present time I have under observation, in the infirmary, a young man whom I first saw about a week ago. He had been run over by a heavy wagon, sustaining a fracture of the base of the skull, with a hematoma in each eye, and he had bled profusely from both ears. I did not attempt operation for the reason that he had no focal symptoms pointing to any localized lesion, and also for the very good reason that, following immediately upon the heels of the accident, there had been an escape of blood from the ears which lasted several hours, as well as a profuse flow of cerebrospinal fluid from the ears, and this accomplished what I would have done by a decompression operation. Nature took care of his brain and relieved it of the tumor which might have formed in the cranial cavity by allowing a free escape of cerebrospinal fluid. To-day this man has a practically normal temperature, with a pulse ranging from 60 to 80; and, with the exception of double vision which developed a short time after the injury, he seems to be in pretty fair shape and is taking light nourishment. He had a dilated and fixed right pupil, which is the only local lesion that can be seen in this man.

J. Garland Sherrill, (Closing): I regret that, because of lack of time, I did not read the entire paper. Some of the points about treatment that have been brought out were covered in the paper.

I think the case reported by Dr. Abell is illustrative of a very important class, and I am of the opinion that such cases get well just as readily

without the decompression operation as they do with it; in other words, I do not think decompression is of much value in fractures of the base. In some instances of fracture of the vault, I have seen this occur: The patient will be unconscious and show evidences of pressure, but without focal symptoms, and when the skull is opened it is found that the brain is not pulsating and bulged out. If you cut the dura the brain bulges so that it is difficult to suture the dura and you have a very difficult operation. With a number of small hemorrhages into the brain and laceration of brain tissue, you are unable to relieve the tension by operation. I have never seen a case get well in which the brain did not expand up to its normal level after removal of a blood clot. I do not recall a case that got well where the tension was very great and the pulsation was not relieved by opening the dura.

I did not mention puncture of the spinal cord as a diagnostic measure for this reason: It is a dangerous procedure. When you withdraw fluid from the cavity of the spinal cord, you withdraw just that much fluid from the cranial cavity. The pressure below is lessened very suddenly, and the pressure above, being very great, is apt to force the medulla oblongata and the pons into the spinal canal very quickly, which may result in respiratory failure and death.

I have seen recent reports on the decompression operation where marked benefit followed this procedure; but, as Dr. Abell has said, it seems that these patients will get along just as well without it. It is possible that laceration of that portion of the brain that controls the development of heat may be responsible for the high temperature, and it is also possible that the patient may have a thin layer of blood at the base of the skull which may give rise to an elevation of temperature, but a sudden development of high temperature looks more like laceration of brain tissue, and I believe these cases get along better without decompression.

A Voice: Do you favor the administration of hexamethylenamin in large doses with the object of forestalling the possibility of infection in the brain? Would you advise washing out the ears or merely wiping them out?

J. Garland Sherrill: Under the head of "Treatment," in my paper, I described the method of cleansing the ears that I prefer. I consider it dangerous to irrigate the ear canal. We may rupture the drum, or lacerate the wall of the canal, so that blood can pass through and possibly carry infection within. I do not use peroxide for that reason. If I use any antiseptic at all it is alcohol on a sponge, or I simply use a moist sponge sufficient to take up the fluid in the canal.

I did not mention the use of hexamethylenamin in my paper, but I believe it is very valuable as a means of preventing infection in the brain.

LA-GRIPPE.

By S. SCOTT PRATHER, Louisville.

My decision to present this subject to the society to-night is to endeavor to bring forth a discussion as to the treatment of this greatly maligned disease. The large majority of you possibly think that la-grippe is a disease of minor importance and hardly worthy a serious thought, only a cold in the head, or a very slight disturbance that will be easily overcome by taking a dose of calomel and quinine, filling your patient up on acetanilid, phenacetine, antipyrine or some of their derivatives. In my opinion this is unquestionably one of the hardest and most difficult diseases that the general practitioner has to combat, on account principally of the after effects. Please do not confound la-grippe with coryza or a slight cold, for we know the former is an acute specific infectious and contagious disease, it is sporadic, epidemic and pandemic. We first learned of this disease in the winter of 1889-90, when it was pandemic. The cause of la-grippe is a minute, non-motile micro-organism, (the bacillus of Pfeiffer) which is capable of manufacturing toxins which possess great depressing power as well as by some unknown way, possibly by lowering the vitality, opening the way for infection of the tissues by other microorganisms. The bacilli can easily be obtained from the sputum in the early stages of the disease. How the bacillus produces the disease is not very well understood, one attack often predisposes to subsequent ones. The exact source of contagion from personal contact is rare; it seems as though the disease came from the saturation of the poison in the atmosphere. We may possibly prevent an attack by building up or toning up the system of one with lowered vitality thereby increasing the resisting power. In the great majority of cases the onset is sudden with chilly sensations or chills followed by fever of from 101 to 105 degrees F., rapid pulse, intense shooting pains in eyes, head, joints and muscles all over the body. We also have chilliness along the spine, sneezing, coryza, eyes water, sometimes hoarseness, sore throat, and often a very troublesome dry hacking cough, the tongue is furred. Sometimes indigestion, nausea, vomiting or diarrhoea. Depression and debility intense, out of all proportion to the symptoms. In mild, uncomplicated cases the fever terminates by crisis in from three to six days. The complications most frequently encountered are first and foremost lobar and broncho-pneumonia, then spinal meningitis and cardiac-neuroses may be encountered. The sequelae may be phthisis, insanity, insomnia, neuralgia, neuritis, neurasthenia, headache, and enlarged

lymphatic glands, especially is the nervous system affected causing affections of the brain, spinal cord and peripheral nerves. The frequency of suicide and neurasthenia after la-grippe has often been noted.

It is very important that we recognize la-grippe as soon as possible and not call it spinal-meningitis as has been done quite frequently of late. The earlier we begin treatment the better. We must bear in mind the suddenness of the attack, catarrhal condition, general malaise, intense depression and intense pains practically all over the body, but may be localized. Isolated cases may be mistaken for a number of diseases, especially typhoid fever or acute bronchitis.

The prognosis is good in an uncomplicated case; care should be exercised by the physician in watching the action of the heart and kidneys and at the first sign of either failing to perform their full functions then they should be assisted by giving a cardiac stimulant or a diuretic as the case may be. Nearly all existing diseases are aggravated by la-grippe, therefore I want to emphasize the necessity of carefully watching the patient who has any cardiac trouble, nephritis, or any disease of respiratory organs. It is my custom when treating a case which I have diagnosed as la-grippe to order a hot bath, the patient gets a great deal more relief from hot baths than from cold—patient put to bed, covered up well to allow free diaphoresis, administer a good purge, preferably podophythin gr. 1-12; aloes soc. calomel each 1-2 gr.; sodium bicarb. gr. 1; pulv. rheu. gr. 2 1-2 in each capsule, giving one every two hours and prescribe for any special condition that may be found. As a good cough remedy for the dry, hacking cough, the benzoin vapor; for catarrhal conditions, quinine in large doses at first, then in small and long continued doses. The after-effects of la-grippe are depression and this depression is decidedly increased by the continued use of coal tar derivatives. We must realize that acetanilid should not be used at all, that phenacetine, its derivatives, as salophen, lactophenin, exalgine, etc., produce blood changes and collapse, that synthetic salicylic acid and its products as salol, salophen and aspirin produce very unpleasant and sometimes fatal heart complications, that antipyrine and its products salipyrine and pyramidon, especially in fever, may produce collapse. We should never use them in continued fevers in large doses because the cause of the lesion is not removed and their bad effects there is a retention in the blood and the recovery of the patient is delayed. We may use these drugs occasionally but it must be done to meet indications only and not for too long a time. Diet, restricted practically to liquids, sometimes allow milk toast with

pounded egg, no acids to be taken, sweets restricted to keep the stomach in good condition. Patient kept in bed for at least two days after normal temperature has been established. Have them gradually to take exercise, partake of semi-solid food and give a raw egg in half a glass of sherry wine three times a day through convalescence. Give them a tonic of strychnia and pepto-manganate iron and manganese for quite a while after they think they are well.

By carefully watching the kidneys, heart and respiratory organs, thorough elimination by the skin and bowels, proper regulation of diet, you will soon have a well and grateful patient who will ever sing your praises and pay your bill.

DISCUSSION.

Virgil E. Simpson, (Said in part): That phase of la grippe which has impressed me most profoundly, is the after effect—the impression made upon the nervous system, the influence upon the cardiovascular, system, etc., which are oftentimes serious and, in not a few instances, result fatally.

The impression made upon the nervous system of the patient is a most profound one, and recovery from this clinical type of the disease has been the most tedious, protracted and least satisfactory of any form that I have encountered.

Early in my professional work I was taught to have the most profound respect for la grippe. During my service as an interne in the City Hospital, in securing the histories of the many persons that passed under our observation throughout the year, it was a revelation to me to observe with what frequency patients would date the beginning of their present trouble from the time they had suffered an attack of la grippe. There is no question in my mind that, while the acute manifestations of la grippe are most distressing to the patient and cause considerable worry and concern, the most serious phase of the disease is the after-effect. We can never be certain just when we are rid of the disease and its sequelae. It is a most treacherous condition, both in the acute symptoms and the more remote manifestations. So far as the acute condition is concerned, it not infrequently occurs that, following a course of treatment of any sort that the physician may elect, the patient is apparently on the high road to recovery, and in a few days he is called back to find confronting him a condition as bad or worse than the initial attack.

Wm. A. Jenkins: La grippe, as a clinical entity, is more to be dreaded on account of its possibilities than because of the condition itself. This is particularly true because, in many instances, the initial attack is so mild that the individual is not forced to leave his occupation and go to bed, as ought always to be done, because where this is not done, the patient is prone to

have a secondary attack such as the last speaker has just mentioned.

As a rule, the force of the disease expends itself upon one of three systems—the respiratory, gastrointestinal, or nervous system. As a matter of course, then, the symptomatology, pathology and plan of treatment must be worked out in each individual case according to the system that bears the brunt of the attack.

The toxin manufactured by the bacillus of grippé seems to have an especial predilection for the nervous system and the cardiac mechanism; it seems to have the power of combining with the neurons, or with the cardiac muscles, and it is these conditions that give us the greatest amount of trouble.

So far as treatment and general management of the disease is concerned, in the main I agree with the essayist. I think a patient with the grippé is best off in bed, where he can be watched carefully and carried through to convalescence under appropriate treatment. However, I certainly disagree with the essayist in regard to the use of phenacetin or other of the coal-tar series, in the febrile aching stage of the acute disease.

I believe that, when a person is first seized with intense rigors, intense pain in the joints and limbs, high temperature, chattering teeth, etc., we get a specific action from remedies selected from three groups; namely, the salol group, the coal-tar group, and the salicylate group. A combination of these three remedies will break the brunt of an attack more frequently than any other drug I know of. The patient is made comfortable, because bathed in perspiration, the temperature lowered and the pain relieved, and I do not believe that, used in this way, there is even a remote possibility of these drugs affecting the cardiac muscle. It is not drugs that do the damage to the cardiac muscle; it is the toxin manufactured by the bacillus.

The nervous type is, of course, the hardest to manage, but in any type the patient should be watched through the attack and should not be permitted to get up and about, and go back to work as soon as the pains are gone. They should be told, in every case, of the possibilities of this disease and should be kept under observation and treated accordingly.

J. Rowan Morrison: I once heard a man read a paper on "Just Mumps," and I think too many of us are prone to refer to this condition as "just grippé." Personally, I have learned to speak very respectfully of this disease. It is certainly potent for a great deal of harm. I do not think the ordinary layman has near the respect for la grippé that he should have, because, whatever our treatment may be, the patient usually gets better after a few days, unless it is a very severe case, and then he wants to resume his ordinary occupation and go about from place to place, and it has been my experience that when this is done, the individual invariably suffers a relapse and

gets worse, and it is this that lays the foundation for the various sequelae which lead to such distressing after-results.

That la grippé is a serious infection there is no doubt. There are many cases of so-called la grippé that are not really grippé, but are simply due to weather conditions producing a myalgia, mild attacks of tonsillitis, and other conditions which the physician as well as the patient attributes to la grippé, but careful observation will show that these cases do not have a rapid pulse, and other characteristic manifestations of la grippé. Although, as Dr. Jenkins has stated, the attack may very often be a mild one, still, even in the milder form, there is almost invariably an acceleration of the pulse, and some depression following.

I agree with the last speaker in regard to the treatment of this condition. The first and most important thing is rest. A patient with la grippé, even though it be a mild attack, should be put at rest in bed for some time, and where the condition is severe the rest treatment should be carried out for a considerable length of time. The nutrition of the patient is affected, because we have a true toxemia to deal with, which has a very distressing effect upon the nervous system, and through that upon the heart. Therefore, it is very important that the nutrition should be maintained—just as much so as in typhoid fever, or any other condition of that kind, because we have here, not only a toxemia, but a febrile condition that requires a considerable amount of nutrition.

I think it is right to give these patients something to relieve the pains which they ordinarily have in the earlier stage of the disease. As a rule, the types of drugs mentioned by Dr. Jenkins are used for this purpose. They are good drugs, and I do not see any reason why they should not be used with discretion, any more than I see any reason why digitalis should not be discretely used in heart disease. The patient should be put to bed in a warm, well ventilated room. Then the supportive types of drugs come into play.

As Dr. Prather has said, a great deal depends upon whether the patient is willing to stay in the house and keep quiet until his nutrition has properly recovered. A very important thing to look out for is the condition of the heart. As has already been stated, this disease lays the foundation for old latent conditions to actively manifest themselves. We frequently see heart conditions brought out by an attack of la grippé. Tuberculosis is often brought to a stage where it runs a very rapid course, after the patient has suffered an attack of la grippé. These and many other complications and sequelae make it imperative that we look upon la grippé as a very severe condition.

Another important thing is the care of the throat and nasal passages during an attack of la

grippe. The teeth and mouth should be kept scrupulously clean, and some simple throat solution or spray should be used. If possible to do anything in the nose, some mild spray should be used there. In other words, the thing is to use some simple and non-irritating means of keeping the air passages and oral cavity as clean as possible. By this means some of the conditions that give our friends, the eye, ear, nose and throat specialists, a great deal of work every spring could be prevented.

W. T. Bruner: The subject of la grippe is very interesting to me because of its complications and sequelae, particularly about the nose and throat, and also the ear. This disease frequently begins with a coryza, and in looking after the nose, particularly in the stage of severe coryza, we should be very careful about using a spray. The mucous membrane is highly congested as a rule, and bleeds very easily, and the use of a spray is apt to cause it to bleed and do more harm than good. If a spray is used in the beginning of the coryza, it should be an oily preparation and not a watery solution, and it should be used in a nebulizer that breaks up the oil particles. These oily preparations do not give rise to any irritation, but, on the contrary, are quite soothing to the mucous membrane.

La grippe is often followed by inflammatory troubles about the nose and accessory sinuses, and we frequently see severe middle ear trouble from it. I wish to enter a word of protest against the use of quinine in this condition. I do not think it should be used, for the reason that it has a bad effect upon the mucous membranes of the nose and throat as well as the ear. I recall a case that I saw about two years ago in a boy twelve years of age, who was rendered completely deaf, evidently from the use of quinine. He had taken only six or eight grains in two-grain doses, and was completely deaf. He was under my care for a month and did not improve any. Then he went back to Florida and I have never heard from him since. I do not know whether he has recovered his hearing or not.

La grippe is often followed by serious trouble in the upper respiratory passages, and these should be carefully looked after in all cases.

Bernard J. O'Connor: I have always looked upon the diagnosis of la grippe in a great many cases with a great big question mark. The average doctor uses the term la grippe with the same freedom that the vast majority use the word rheumatism; both are used to cover a great deal of ignorance. That we have sporadic and epidemic types of la grippe is an unquestionable fact. Any one who has ever made a considerable number of sputum examinations knows that many specimens contain the bacilli of influenza in predominant numbers. A positive diagnosis of la grippe without a sputum examination, is a very difficult problem. I have seen so many mild and severe types of infection, not

grippal in nature, but which were diagnosed as such, that I always regard such diagnosis with a great deal of doubt.

One point brought out by the essayist in regard to the pathology of la grippe has been contradicted by many of the best authorities in this country and in Europe. In a long article which appeared in a recent number of the *Journal of Experimental Medicine*, detailing the results of autopsies in eight cases of la grippe, it was stated that no trace of lobar pneumonia could be detected in any of these cases. Lobular pneumonia is about the only true type of pneumonia that comes from influenza.

The essayist made the statement that a great many cases of la grippe are diagnosed as cerebrospinal meningitis. I hope that the symptoms of the latter condition are never sufficiently cloudy to lead one to make this mistake. However, we do have in influenza, an influenzal meningitis that is somewhat similar in its pathology and symptomatology to the cerebrospinal type.

As to treatment, I do not know that I can add anything to what has been said. I do not like straight quinin. In large doses it is apt to give the patient a feeling that is almost as bad as the disease for which it is given.

The essayist made the statement that the synthetic salicylate of soda is very detrimental to the blood and is not to be advised. Experiments made by the board recently appointed by the American Medical Association, have shown that the synthetic preparation is almost as reliable and beneficial as the natural.

A. W. Nickell: I want to agree with Dr. O'Connor as to the pathology of la grippe. It has been demonstrated that, in epidemic influenza, all of the symptoms referable to the respiratory form of the disease have been largely of the type of broncho-pneumonia.

As regards quinin, I am opposed to that mode of treatment, but a great many leading authorities are using euquinin and claim to be getting very good results from it.

I also want to agree with the gentleman who advocated the synthetic salicylate treatment, except in regard to acetophenetidin. I combine caffeine with that and alternate with salpyrin, and I have never seen any cardiac depression from it such as we get from the straight coal-tar derivatives.

Just another word in regard to the respiratory form of this disease. Where there is a rather slowly resolving pneumonia and possibly a bronchitis lasting for some time after the patient has partly recovered, the use of carbonated creosote, in 30 to 40 drop doses, every two or three hours, has given me the best results of any preparation I have ever used.

S. Scott Prather, (Closing): In closing I wish to call attention to one point that was brought out in the paper. I stated that it is my custom, in treating la grippe, to always put the patient to

bed. This seems to have been overlooked by some of the speakers.

I also wish to call attention to the fact that I did not say we should not use any of the coal-tar derivatives, but that their use should not be continued over a long period of time. They should be used to meet the occasion only, and not continued for too long a time.

I also made the statement, in my paper, that "all existing diseases are aggravated by la grippe; therefore, I want to emphasize the necessity of carefully watching the patient who has any cardiac trouble, nephritis, or any disease of the respiratory organs." Of course, if a patient has heart trouble, or tuberculosis, or anything of that sort, an attack of la grippe will aggravate it. The use of the coal-tar derivatives in moderation, and under the care and watchfulness of a physician is all right, but we all know persons who take as much as forty or fifty grains of aspirin a day, and phenacetin the same way, and I do believe that this is injurious.

As to Dr. O'Connor's remarks in regard to cerebrospinal meningitis, I will say that I know of one doctor who diagnosed five cases of la grippe as cerebrospinal meningitis during the epidemic of the latter disease here last spring.

PARINAUD'S DISEASE

(WITH REPORT OF CASE.)

By J. H. SIMPSON, Louisville.

I feel that I must apologize for this paper coming under the head of an essay, because of the limited knowledge we have of this disease, and it should more fittingly be described as a case report.

Parinaud's conjunctivitis is one of the rare conditions of the eye little seen by us, although it is most common in the temperate zone.

It is supposed to be of animal origin, but as yet no microorganism has been isolated.

It is unilateral and the onset is similar to that of acute trachoma; also the elevations are like unto trachomatous follicles, except that they are more or less pedunculated and often occupy sites upon the bulbar conjunctiva. The preauricular, retro-maxillary and cervical glands are usually enlarged and oftentimes one or more suppurate.

I have given you a brief outline of this condition in order that you might follow more closely the case I have to report.

The late Dr. T. C. Evans asked me, sometime before his death, to report the following, and I have taken this opportunity to do so.

During the summer of 1910, a gentleman from the southwestern part of the State, accompanied by his son, aged twelve, came to the office for consultation regarding the condition then existing in the child's right eye.

PREVIOUS HISTORY.

Boy had numerous diseases of childhood. Several years before left eye had been removed because of penetrating injected wound of eyeball. For about ten days previous to this visit, the child had been suffering with great pain in head accompanied by chills, and high fever, with hallucinations and which was diagnosed as meningitis.

Upon examination we found:

OBJECTIVE SYMPTOMS.

Thickened and oedematous condition of right eye lids; palpebral and ocular conjunctiva very red and angry-looking; one or two pedunculated bodies, grayish red in color about the size of an hemp seed, just above sclero-corneal margin and to the right of the perpendicular meridian. To the right of this was a larger body with erosion of the apex. There were several more of these bodies scattered over the ocular conjunctiva, having distinct ulceration within the sulce between.

The right preauricular gland was much enlarged and suppurating. The retro-maxillary and some cervical glands were enlarged.

The diagnosis of Parinaud's conjunctivitis was made and patient referred to Deaconess Hospital where purge, irrigation of saturate solution boric acid z 1 h. and instillations of argyrol z 4 h. were ordered.

After several days the swelling, pain and fever had subsided and realizing the length of time generally allotted to the ultimate recovery of these cases the boy was allowed to go home, he making an uneventful recovery in several weeks.

DISCUSSION.

W. T. Bruner: This case is very interesting because of its rarity. It is an extremely rare condition of the conjunctiva, and from the literature we would infer that very little is known about it. Some of our text-books do not even mention it, and those that do give only twelve to fifteen lines description of it.

As the essayist stated, it seems to occur among those who are about animals a great deal. One interesting feature about this case is the time of recovery; they usually take a much longer time for recovery than in this case. It is described by some authors as a lymphoid condition of the conjunctiva, and by others as polypoid condition, resembling very much the polypoid growths found in the nasal passages. The condition is usually unilateral, and an interesting feature of it is the great involvement of the lymphatic glands of the same side, indicating that it is a lymphatic condition of the condition of the conjunctiva.

J. H. Simpson, (Closing): I have nothing to add in closing except to corroborate what Dr. Bruner has said. I am sorry Dr. Ray is not here, because he also saw this case and it was with his help that I made the diagnosis.

CLINICAL CASES.

GONORRHEAL RHEUMATISM.

(PRESENTATION OF PATIENT AND REPORT OF CASE).

By J. A. O. BRENNAN, Louisville.

This man, who is a policeman, has been under the observation of myself and others for about six years. When he first presented himself, both feet and both knees were involved. I have tried everything I have any confidence in for this trouble, but he does not seem to improve at all. The soreness and swelling that he formerly had in the knees has vanished, and the trouble is all in his feet now. Under vaccine treatment the old gonorrheal condition subsided.

Dr. W. B. Owen saw this man about a year ago, and fitted him with a brace for his foot, and without the brace he does not seem to get along at all. He is a policeman by occupation and it is essential that he get around a good deal. Fortunately, however, he is a mounted policeman.

I have given him very little treatment up to a month ago when I tried the Schafer vaccine on him, but I have been unable to see any results from it. He refuses to have it any more because of the terrific reaction, from which he suffered a great deal. I gave him the last injection in the leg because the arm was so sore.

I had an X-ray picture of the foot made, thinking he might possibly have some exostosis there, due to the old gonorrheal condition, but it revealed nothing of importance.

I would be glad to have you inspect the foot and give your opinions.

DISCUSSION.

Edwin T. Bruce: About one year ago this gentleman was referred to me by Dr. Brennan for a radiographic examination of his foot, and at that time a diagnosis of flat-foot was made. We know that, in this condition, the pain is often referred to the knee and also to the thigh; there is always swelling and very great discomfort. I think the solution of this man's trouble would be a properly fitting arch, and that the condition is nothing but simple flat-foot.

Jno. B. Richardson: This looks to me like more than a weak foot. I think the term "flat-foot" is a bad one to use, because a great many weak feet are not flat, the arch showing no evidence of breaking down.

The first thing I noted in looking at this case was the very bad shoes the man is wearing. As a primary measure, I think his shoes should be changed.

Dr. Bruce made a good point when he suggest-

ed the application of properly fitting plates. The plates he is wearing are old and it would probably be a good plan to have a new cast taken and properly fitting plates made.

Bernard J. O'Connor: Along mechanical lines, one point that has not been mentioned is the benefit that follows certain exercises in this class of cases. Wilson, of Philadelphia, lays more stress upon the importance of exercise of the muscles than he does upon the application of an arch; in fact, he claims that, in many cases, an arch will do harm by giving artificial support and causing the ligaments, through pressure, to atrophy. He advises exercise with resistance, to be carried out several times a day after a hot foot-bath.

Another important point is the manner of walking. As a rule, these patients walk with the toes turned out, and in that way throw all the weight directly upon the inner side of the arch. They should be instructed to walk with the toes turned in, so as to throw the weight on the outer side, and the strain will not be so great. The same thing applies to standing; instead of standing with the toes turned out, they should be close together.

W. W. Klein: I agree with Dr. O'Connor that the value of massage and exercises in these cases is often underestimated. It is really wonderful what results we can get in these chronic conditions by the employment of passive motion in one form or another. Often when a case of this kind is put under a proper course of treatment, while the response is usually slow, the condition will get gradually better until the patient himself hardly realizes the result that has been obtained. I recall one case in particular in which massage was practiced persistently—every day—for a month and a half, and the result was very marked indeed.

Speaking of gonorrheal arthritis in general, I want to call attention to the use of extremely high temperatures of dry heat. Subjecting the affected part to a temperature of 500 to 550 degrees F., for a hour or an hour and a quarter, will produce a superficial burn and very often will correct the condition entirely.

W. Barnett Owen: I had the pleasure of seeing this case with Dr. Brennan a year ago and while the condition is better to-night than it was at that time, still there is something more needed.

I hardly believe this is a case of simple weak-foot, because there is not enough rigidity. The patient can easily throw his foot into several positions. He has obtained some relief from the brace, which was made from an actual cast of the foot. It was trimmed out over the inner border to throw the foot in and give as much pressure as he could stand at that time. I believe it would be a good idea to make another brace, putting more pressure on the inner border of the

foot in order to throw the weight on the outer side.

He has had massage—all that he could stand, and has also had hot fomentations, hot-air, etc. Dr. Brennan has sent him to the best men in each line in the city, and I believe he has made a thorough study of the case. Still I hardly think the patient has gotten what he needs.

J. A. O. Brennan, (Closing): I wish to thank the gentlemen for their liberal discussion of the case.

I do not think there is any question about it being a gonorrheal condition. To my mind, it is something more than simple weak foot. The X-ray picture shows distinctly the condition that existed, and the question came up at that time as to whether or not it was flat-foot. I suggested that there might be something on the os calcis, the removal of which would do him good. Dr. Moren treated him with electricity for a while, with only temporary benefit.

The intravenous injection of the Schafer vaccine might do good, but it is hard for him to lose time from his work. I have had good results from the vaccines in other conditions, such as epididymitis, chronic gonorrhea, etc., and it might give good results in this case, but it would be necessary for him to go to the Infirmary for a while.

I think I will adopt the suggestion to get another arch made.

ACUTE ARTICULAR RHEUMATISM TREATED WITH PHYLACOGEN.

(REPORT OF CASE.)

By EDWARD B. RICHIEY, Louisville.

Mrs. H., age 65, white, female, married, housewife.

DIAGNOSIS.

Chronic articular rheumatism.

HISTORY.

Mother of eleven children, seven of whom are living and in good health. Husband, age 70, in good health and very active. Father died at the age of 64, cancer of stomach. Mother died age 30, childbirth. One brother living in good health; three brothers died in infancy. No sisters. Usual diseases of childhood; no history of rheumatism in family.

SYMPTOMS.

Subjective: Thirteen years ago feet and ankles pained when first getting up in the morning. Went to "Springs" that summer but received no benefit. One year later knees hands, fingers and elbows became involved necessitating the use of crutches at times. Eight years ago had to resort to crutches all the time and then had great difficulty in get-

ting about and suffered great pain, unable to turn in bed without assistance.

Objective: Slight seal-fin deformity of both hands; both knees and both elbows slightly ankylosed; pain in all these joints, also in hips and shoulders; cannot turn in bed without assistance. Has been unable to walk, even with assistance of crutches, for past three months. Suffers with insomnia on account of pain, appetite poor; vertigo; practically bed-ridden; is very fat and heavy.

TREATMENT AND RESULTS.

Spent one winter in the South, has taken all the rheumatic remedies, osteopathy, hot baths, constitutional and local measures, with only very temporary relief and a return of former pains much exaggerated.

February 8, 1912.—Rheumatism phylacogen, 2 c.c., subcutaneously. No reaction, systemic or local; no change in symptoms. Temperature, pulse and respiration normal.

February 9th.—Rheumatism phylacogen, 5 c.c., subcutaneously. No special reaction noted. Ate hearty dinner. Kidneys very active. Temperature, pulse and respiration normal.

February 10th.—Rheumatism phylacogen, 7 c.c., subcutaneously. Temperature slightly subnormal; appetite not so good; somewhat depressed.

February 11th.—Temperature, pulse and respiration good; appetite normal; no phylacogen to-day.

February 12th.—Rheumatism phylacogen, 2 c.c., *intravenously*, given very slowly (four minutes time). Thirty minutes after injection had chill lasting 55 minutes. Nausea, vomiting, headache, occasional blindness; very thirsty. Maximum temperature 103; pulse 120. Reaction gradually subsided; slept well, turned in bed without assistance and ate fine breakfast next morning.

February 13th.—Rheumatism phylacogen, 4 c.c., *intravenously*, taking five minutes' time to give injection. Forty minutes after injection had chill lasting 20 minutes; severe headache; temperature 102.4; pulse 120; pains in joints; numbness over body. Slept very well, and ate light breakfast.

February 14th.—Rheumatism phylacogen, 5 1-2 c.c., *intravenously*; five minutes' time taken to administer this dose. Twenty-five minutes after injection, chill lasting one hour, not so severe as yesterday; no headache; thirsty; very comfortable. Maximum temperature 101; pulse 102.

February 15th.—Rheumatism phylacogen, 8 c.c., *intravenously*. Thirty minutes later had chill lasting 45 minutes; sleeping off and on; thirsty. Maximum temperature 101.2; pulse 108. Light diet; practically free from pain.

February 17th.—Rheumatism phylacogen, 10 c.c., intravenously. Fifteen minutes later had chill lasting 35 minutes; no headache; maximum temperature 101.2; pulse 102; light diet.

February 17th.—Rheumatism phylacogen, 10 c.c., intravenously. Fifteen minutes later had chill lasting 45 minutes. Maximum temperature 99.4; pulse 90; slept in afternoon; felt fine.

February 18th.—Temperature, pulse and respiration normal; slept fine last night; ate heartily; walked on crutches and sat up nearly all day.

In giving the intravenous injections, endeavored to allow about one minute for each c.c.

CONCLUSIONS.

The results in this case are, as the son in a letter to me this morning put it, "almost incredible". The case having continued over a period of twelve years, the patient being unable to move her body, even in bed, when we began the Schafer treatment, justifies the above statement. I heartily endorse its use, but find it necessary to administer laxatives and tonics at the conclusion of the intravenous treatment. Am convinced also of the necessity of extreme care in the technique and in close observation of the patient as to the vital parts during the treatment. I believe the intravenous method is the method *par excellence*.

This patient is practically free from all pain, says she feels better than for twelve years, has free motion, can extend her limbs several inches more than before treatment. She cannot find words to express her satisfaction and gratification.

DISCUSSION.

Oscar E. Bloch: I would be glad if Dr. Richey, in closing, would give his technique for the intravenous injection of the vaccine.

Irvin Lindenberger: I would like to ask Dr. Richey how many injections he gave in all?

Edwin B. Richey, (Closing): In answer to Dr. Bloch's question, of course it is necessary to employ very careful technique in making intravenous injections. In every instance, it is my custom to boil the instrument to be used for an hour and a half, and then to very carefully sterilize the part before giving the injection. In this case the injections were made in the median axilla, in each instance taking five minutes to introduce the needle, very slowly and carefully. After the needle is introduced, always withdraw the blood before injecting the phylacogen, watching the pulse and the general condition of the patient carefully. In no instance did I have any local irritation following an intravenous injection. Of course you know, if you have had

any experience with vaccines (and sometimes with serums), that there is usually quite a good deal of local reaction following subcutaneous injection. This is also true of autogenous vaccines. In this case the local reaction was very decided, and the patient complained greatly because the arm was so sore and tender, and this reaction continued for some time. That is one of the objectionable features attendant upon subcutaneous injection. The first three injections were given subcutaneously. It was my purpose to determine the degree of susceptibility of the patient to the vaccine, which was practically a new thing to me. Consequently, I felt justified in injecting it subcutaneously at first, followed by the intravenous injection, as suggested by Dr. Schafer, following which there was no local reaction. In each instance the needle was introduced into the same vein in practically the same place without any difficulty. I gave three subcutaneous injections and did not get one-tenth of the result that I did with six intravenous injections, making a total of nine injections. I believe that the intravenous injections would have accomplished almost as much without the primary subcutaneous injections. As stated in the report, I think the intravenous injection is the method *par excellence*.

TUBERCULOSIS OF BLADDER.

(REPORT OF CASE).

By HERBERT BRONNER, Louisville.

Patient, C. A. W., age 30; white; married.

FAMILY HISTORY.

Father dead, cause of death, tuberculosis of bowel. Mother living and now in good health, although at the age of thirty she had tuberculous cervical adenitis, for which she was operated. One sister died of pulmonary tuberculosis. Two sisters and one brother living and in good health, one of these sisters having had a tuberculosis of the knee-joint.

PERSONAL HISTORY.

Patient has had measles, whooping cough, mumps, pneumonia twenty years ago; typhoid nine years ago. In August, 1910, patient had first symptom in genito-urinary tract, which consisted of swelling and pain in the left epididymis; one and a half months later, similar symptoms in right epididymis. About the same time, an abscess of the left epididymis was opened and curetted. This wound never healed. Two weeks later an abscess on right side was opened and curetted, and this wound never healed.

In January, 1911, patient came under the observation of Dr. Abell, who found immediate operation necessary. The operation consisted of an epididymectomy on the left side.

and a complete castration with high division of the vas on the right side. The wound on the left side healed completely; that on the right side completely except for a small sinus along the cord. In the latter part of December, 1910, patient first noted bladder symptoms. This consisted of frequency of urination, thus bearing out the statement of Mr. Fenwick that the "hall-mark" of vesical tuberculosis is vesical irritability. Pain, which occurred previous to urination, began in January, 1911. It has been our observation, in vesical tuberculosis, that the pain frequently occurs before urination, rather than during or at the end of urination. Patient first noted haematuria in May, 1911. Frequency and pain became progressively worse, and the patient went to North Carolina in February, 1911, and was put on the tuberculin treatment. This treatment was continued until July 6th, 1911, when the temperature became so high that it was deemed advisable to abandon this method of treatment. Temperature at this time was 103 degrees F. He was then treated for malaria, to no avail. The patient came to Louisville on September 20th, 1911, and was seen by Dr. Abell, who kindly referred the case to me. The condition which we found on this date was as follows.

Patient was having repeated chills; afternoon temperature 104 degrees; he was voiding every fifteen minutes, with considerable pain; he was having severe night-sweats. He was very pale and emaciated and weighed only 130 pounds. The wound along the cord had not healed.

Examination of the urine showed enormous amount of pus, tubercle bacilli, colon bacilli-staphylococci and streptococci.

Examination per rectum showed a very nodular prostate, and slight involvement of the seminal vesicles. This was plainly a case of ascending tuberculosis of the bladder, accompanied by a profound mixed infection.

We did not use the cystoscope in this case, because we felt that the diagnosis was clear, and that instrumentation in a case of this kind, where the prostate was decidedly involved, and where a very irritable bladder existed, would only result in harm.

The patient still believed that his symptoms were due largely to malaria, but we assured him that the mixed infection was largely responsible for his symptoms, and proposed the use of an autogenous vaccine with a view of immunizing him against the infection. To this he readily consented.

The patient began to live out in the open air on a porch a few days after his arrival here, and has done so up to the present time.

The use of the autogenous vaccine, which was made by Dr. Allen, was instituted in the latter part of September, and has been con-

tinued for six months. There was a very decided reaction after the first few doses, so that we found it necessary to lengthen the interval and reduce the dosage of the vaccine in order to avoid too long a negative phase. After these first few doses, however, the negative phase, while decisive in character, was never longer than 24 to 36 hours, and was always followed by a good positive phase. The patient's temperature dropped steadily under this treatment, and reached normal by the end of December.

PRESENT CONDITION.

Temperature normal during the entire 24 hours. Weight, 179 pounds, a gain of 49 pounds. Patient looks hardy and rosy and rugged. He urinates every three hours in the day-time and every two hours at night. The urine has cleared up considerably, although still showing some pus.

The sinus along the cord healed up in October, 1911, four weeks after beginning the use of the vaccine.

Our reason for reporting this case is to show, somewhat, the possibilities of treatment in a class of cases which have heretofore offered but little. Our further plan of treatment will be to continue the use of vaccine and to begin the careful use of tuberculin. We will be glad to report further in this case.

DISCUSSION.

Irvin Abell: As Dr. Bronner has stated, I operated upon this man, after which he passed from my observation, going to North Carolina. I had several letters from him and one from the doctor in the case, who reported vesical hemorrhage.

This case speaks remarkably well for the use of the vaccine, as evidenced by the tremendous improvement the man has made.

In addition to the good influence of the vaccine, I would like to call attention to what should be done, I believe, in young men who are the subjects of tuberculous epididymitis. We know that this occurs most frequently during the period of actual sexual life—say between the ages of 15 and 35. Frequently, the disease extends up the vas, involves the prostate, and extends down the opposite vas, so that when there is involvement of one side, it is usually only a few months until the same condition exists in the other side, necessitating complete castration and consequent deprivation of the sexual power, which is very undesirable. In this case, removal of the epididymitis, leaving nothing but the body of the testicle, with removal of a portion of the spermatic cord preserved the sexual ability. The testicle at this time seems to be perfectly healthy, and at the time he presented himself in this city, in September, seven months after he was operated upon (at which time I was out of town and Dr. Bronner took charge of the

case), he had no evidence of any disease in the left inguinal canal. I think Dr. Bronner is to be congratulated upon his scientific handling of the case; the results speak eloquently for it.

Ellis S. Allen: I did not see this gentleman before he was operated upon, but I saw him last summer when I made a blood analysis for Dr. Abell to determine whether or not he had malaria. The improvement that has taken place in this man is marvelous, and I have seen other cases of bladder infection and infections of the urinary tract, in which remarkable improvement followed the use of autogenous vaccines.

I believe that where we get our best results from vaccines is in those conditions where the vitality of the patient has become so lowered that their fighting forces, so to speak, are unable to destroy enough bacteria to liberate the endogenous toxins in sufficient quantity to generate immunity, in which event we have to inject into the patient bacteria that have been killed for him, or the chemical capsule destroyed and the intracellular toxin liberated, which stimulates the enzymes of the cells and brings up the immunizing powers of the tissues. I had a case not long ago in which the appendix and about an inch of the cecum were gangrenous. I closed the cecal openings as well as possible, expecting, of course, a fecal fistula. Anticipating a terrific amount of infection, I at once instituted vaccine treatment. To our surprise (and we attributed it to the vaccine) very little pus developed in the wound; there was no discharge, no fecal fistula, and the patient made a rapid recovery.

A month or two ago a young man came under my care with a terrific cystitis. Cystoscopic examination showed numerous large ulcers in the bladder. Tuberculosis was suspected and numerous microscopical examinations were made for tubercle bacilli, without results. However, the urine showed the presence of a mixed infection, staphylococci, streptococci and colon bacilli being found in it. An autogenous vaccine was made and I have been using it on him now for about two months. Previous to this I did a perineal section and drained the bladder, but he still had frequent urination and a great deal of pain, and I therefore resorted to autogenous vaccine. He is just about ready to go home now with the fistulous tract closed.

I know of no class of cases in which vaccine treatment does so much good as in chronic infections of the genito-urinary tract. I have in mind a physician of this city who, for some time, had a tuberculous kidney with a colon infection engrafted on it. After several months' treatment with tuberculin we were no longer able to demonstrate the tubercle bacilli in the urine, but it swarmed with colon bacilli and contained a great deal of pus. An autogenous vaccine was made and administered and in two or three months the urine cleared up entirely. I would certainly advocate vaccine treatment in chronic infections,

and we are now beginning to get almost as marvelous results in acute infections.

W. C. Dugan: I think Dr. Bronner is to be congratulated upon the result obtained in this case, and that the society is to be congratulated upon having the opportunity to see such a result.

I have seen two cases in which double castration was done. One of these patients first had a chronic sinus. Just as Dr. Abell stated, the second testicle frequently becomes involved, and in this case the patient developed an acute miliary tuberculosis of the other testicle, with all the symptoms of a general tuberculosis, night-sweats, temperature, etc. It was necessary to do a second castration, the first testicle having been removed six months previously. This man also has vesical symptoms, painful and frequent urination, etc. As Dr. Bronner has well stated, in tuberculous conditions of the bladder, the pain often precedes urination. This man had the most violent vesical symptoms. The prostate was very much enlarged and it was thought at one time that it would be necessary to do a prostatectomy, but his vesical symptoms gradually disappeared and the enlarged prostate subsided. A number of years later when I examined him, it was just a mass of hard, calcareous material. He told me that he still had the sexual desire.

I recall another case, very much like the first one, except that this man had a double traumatic tuberculosis, following an injury to his testicles sustained in a runaway accident. The diagnosis was verified by microscopical examination. The man became emaciated until he hardly cast a shadow. We did a double castration, removing both testicles well down toward the bladder. He had vesicle symptoms, the prostate was involved, and he weighed at that time only a little over a hundred pounds. His physician told me recently that his weight is now about 60 pounds, his vesicle symptoms have been entirely relieved, and he has retained his sexual power.

Herbert Bronner: I will say that, so far, this patient has had no diminution of his sexual ability.

DISSEMINATED SCLEROSIS.

By F. C. ASKENSTEDT, Louisville.

Disseminated sclerosis is, according to Oppenheim, of all chronic organic diseases of the central nervous system, the most common. As compared with all other maladies of the nervous system it is, however, relatively rare. Investigating 70,000 neurological cases in America, Bunker found it in only 0.58 per cent. The symptoms of disseminated or multiple sclerosis are due to the presence of plaques or indurations in the brain and spinal cord, most frequently in the pons, the internal capsule, the centrum ovale of the brain, and in the lateral tracts of the cord. These plaques are formed by a degeneration of the

myelin substance of the neurons and a proliferation of the neuroglia and surrounding connective tissue, the axis cylinders, proving more resistant to the destructive process, are often seen to pass through the new formed tissue. This explains the transient appearance of symptoms noticed more especially in the early stage, and the evident irritation and paresis.

The recognition of the disease at this time is not always easy, hysteria, brain tumors, dementia, syphilis, cerebellar atrophy, multiple encephalo-malacia, often having been mistaken for the disease. Oppenheim mentions spastic spinal paralysis, nystagmus, slowness of speech, attacks of vertigo, and forced laughter as early symptoms of disseminated sclerosis.

Thirty per cent. commence with optic atrophy. Strumpell and Muller have called attention to the disappearance of abdominal and cremasteric reflexes as an early sign. Daux speaks of short hemiplegic and paraplegic attacks, with sensory disturbances occurring during its incipency.

The remarkable remissions of symptoms and sometimes of apparent recovery during its advent should put us on guard against diagnostic and prognostic errors, although a few cases have been known to make permanent recovery.

The patient I bring before you this evening presents no new or unusual feature. He is of interest to those only who are not quite familiar with the symptom complex and course of the disease.

The patient was first seen October 18, of last year, and the following history is taken from my records of the above date:

Aged 34, height 6.1 ft., weight 150 lbs. During the last few years has been employed in the refrigerating rooms of a large hotel. Family history shows no organic nervous trouble.

PREVIOUS HEALTH.

In early life patient was in poor health—"sickly" as he states it. Had measles, whooping cough, and cerebro-spinal meningitis (?) as a child. Has been a "rheumatic" all his life. At 15 had St. Vitus dance. In 1909, weighed 160 pounds, his heaviest weight.

PRESENT ILLNESS.

Last January he began to notice that he could not write well with the left hand. A little later he suffered sharp and dull pains through the body, mostly through the shoulders. Then the left leg began to stiffen, after this the right. During the last 4 or 5 months he has had pains, off and on, in left lumbar region. His hearing has been growing worse the last two or three years. Speech

is thick and rather difficult. Is subject to occipital headaches, sometimes extending to forehead, worse in the evening, but relieved by anodynes. These headaches have been growing less frequent and now seldom return. Occasional attack of vertigo, but not to the extent of falling. Memory is failing. He sleeps well, has a good appetite and a fair digestion. Bowels somewhat constipated. There is no twitching of the muscles, but the right arm has spells of shaking, and at times the whole right side becomes tremulous. Since April he sometimes staggers when walking, with tendency to fall to the right. There are fleeting pains in head, right index finger and feet. The sphincters functionate normally.

PHYSICAL EXAMINATION.

Pupils respond to light and accommodation. No tremor in hands on extension of arms, but a large tremor can be noticed at times on voluntary motion ("intention tremor"); none in right leg. Coordination of arms normal. Grip of hands firm. Sense of touch normal in both arms. Romberg sign absent or feebly present. Nystagmus of both eyes or turning them in or out (quick movement away from center, slow returning). Epigastric, right abdominal and cremasteric reflexes abolished, left abdominal present. Scapular reflexes absent. Triceps reflex feeble, but more marked on right than on left side. Patellar reflexes exaggerated. Achilles reflexes normal. Hearing of left ear fair; can hear watch tick thirteen inches from ear; failed to hear the watch when applied to the right, but heard it when applied to right temporal bone. Temperature at 11 a. m., 98.5; respiration 17; pulse 69, sitting; systolic tension 128; diastolic 100; pulse 70, lying. Condyloid gland of right arm barely palpable; of left arm not felt. Through the courtesy of Dr. J. J. Wynn, who examined the patient's eyes and ears, I am enabled to add the following symptoms:

Date, November 16, 1911. Marked nystagmus of both eyes. Worse on looking upward and to sides. Vision of both eyes reduced. Right eye 15-70; left eye 15-100. Pupils react both to light and accommodation. Visual field concentrically contracted in both eyes. Fundus apparently normal. Possibly some slight pallor of disc. No evidence of external eye disease.

Ears. Tinnitus aurium and deafness, worse in right ear; no previous history of pain or discharge. Examination revealed membranum tympani of each ear slightly retracted. In left ear hears watch at a distance of three feet. Rinne test positive. Weber test referred to left. In right ear, Rinne test is negative; hears spoken voice three feet, but

fails to hear watch or whisper. Some post-natal catarrh accounting for retracted tympani and for some deafness, especially on the left side.

No physical examination has been made since the above records were taken, and the patient is brought here this evening that you may yourselves ascertain his present physical condition.

DISCUSSION.

Curran Pope: In the consideration of disseminated or multiple sclerosis, the first question that one has to settle definitely is that of symptomatology. It might be said that disseminated sclerosis is, in this respect, **regularly irregular**; that is to say, cases do not present a regular sequence of symptoms, simply because the different plaques of sclerosis are located at different points in the course of the central nervous system, and for that reason we are likely to have irregularity in the symptomatology. It has always seemed to me that the essential point in these cases is to first eliminate the question of other diseases of the nervous system, notably those cases in which the cord is the first to become involved. Of course, I cannot stop except for a moment, to speak of the classical symptoms of the disease; those who are at all familiar with disseminated sclerosis know what they are.

The pathology is not at all settled. As to what is the causative factor in this condition, I cannot find any two authorities that agree. Most of them seem to believe that it usually follows an infection of some kind, but when it comes to stating what kind of an infection, none of them venture to make an assertion. Others say that there is degeneration of the myelin, while some have advanced the theory that it is possibly due to the short-circuiting of the nerve current on account of the absence of myelin.

I have seen quite a number of cases of disseminated sclerosis. The first experience I ever had with it was in 35 or 40 cases seen in Charcot's clinic at the Salpêtrière, all of them exhibiting more or less classical symptoms, with numerous variations. Those of you who know of Charcot's method of teaching, recall perhaps, that it was his practice to take a group of "classical cases" as he called them, and then have, to one side or another, several groups showing deviations from what he termed the classical group, and in this way one could obtain a most excellent idea of the variations from the classical, if it may be so called. Only those of you who have seen the line-up on the noted Thursday mornings can realize the vast advantages that arise from such a method of teaching clinical neurology.

I noticed that the doctor was exceedingly quiet in regard to therapy; he did not even mention any therapy for this trouble. Personally, I have seen remissions occur. Why, I do not know. I have at times attributed it to one thing and then

another. I have believed, however, that building up the patient's general health has done more good than any other one thing. At one time I was inclined to believe that harnum chloride had an effect upon this trouble in the way of restraining its activity, but I have had that idea shattered on several occasions, and I have given it up. One drug that I have seen do good temporarily is tincture of hyoscyamus, in small doses, given at reasonably short intervals, three to five drops every two or three hours until a certain amount of sedation is produced, and then lengthen the interval. I am not averse to hyoscyamus but I am against hyoscyne. The tincture of hyoscyamus, supplemented by tonics, and particularly by physical remedies, does good. These people are benefitted by massage and by resistive exercises, particularly exercises that have hyperextension and hyperflexion for their object. They seem to act a good deal like they do in Parkinson's disease, paralysis agitans, and I have learned to depend a good deal upon these measures in disseminated sclerosis, especially since I have found no drug remedies of any value whatever save for intercurrent afflictions that may come to these people, just as they come to one in normal condition. Eventually, unless carried off by some intercurrent malady, these patients will pass along to the terminal stage of the disease.

At Rosenthal's clinic, in Vienna, and with Gower, in London, I saw quite a number of these cases, and the specimens I exhibit here to-night were taken from a case that chanced in the clinic there, was followed for several weeks, and died suddenly from an intercurrent malady. They show the varying locations of the disseminated plaques in the central nervous system, brain, cord, etc.

David C. Morton: The interesting feature of disseminated sclerosis, it seems to me, is the peculiar selection of the area involved, and in view of that selection it is argued by some that an infection of some sort—perhaps a yet unknown infection—is at the bottom of it. As Dr. Pope has just said, the infection seems to be in the myelin, with impairment, for a certain time, of the axis cylinder. To begin with, it is a degenerative process, with substitution for the myelin of newly formed tissue.

This man claims to have had a very severe attack of rheumatism a few months prior to the onset of this disease, and to that extent this individual case is rather confirmatory than otherwise of the theory of an infectious disease preceding the onset of the symptoms. He is 34 years old, being in the fourth decennium, which is, according to some statistics, the most selective age of the disease.

Making the diagnosis purely and simply on the symptoms as given, and the signs as elicited, is a very difficult matter, on account of the lack of type of the disease. I think, however,

that the evidence is all in favor of a correct diagnosis having been made in this case.

As to therapy, medicinal agents, apparently, to some extent, give relief. The history of these cases is that they last from five to twenty-five years, with an average of five to fifteen years, nearly all being carried off by some intercurrent affection. Remissions are prone to occur. We often think that we have gotten results from some particular form of therapy, and credit our therapy, and perhaps our ingenuity, with the result obtained, overlooking the fact that multiple sclerosis, when left alone, is characterized by most wonderful remissions. Therefore, we had better think twice, or three times, and then be very careful how we place our faith in this or that measure.

The case is very interesting, and it will be much more interesting to see it later on, possibly in one of these remissions. Some men assert that a mixed treatment of iodid and mercury seems to bring about some improvement, but their observations have been made only in those cases in which remissions may or may not have occurred without therapy. The therapy of this condition is practically nil, so far as I have been able to learn from the records of men who have had a great deal of experience with it.

John J. Moren: I have been impressed by one particular thing in connection with this very interesting disease; that is, its infrequency in this section of the country. It is one of the most frequent of the nervous diseases in foreign countries, but here, at least in this section of the country, we see very little of it. Some time ago Sanger-Brown wrote an article on this subject in which he stated that many cases of multiple sclerosis went undiagnosed. After we have seen a number of cases of this kind, I might think there is something in that statement, but when we watch the development of many of these cases, we find that they do not develop into the typical cases of multiple sclerosis, such as are seen in Eastern clinics. The majority of cases that I have seen in this vicinity have been in persons of foreign descent.

I had a very interesting case at the clinic in the City Hospital, which resembled this one very much, except that the symptoms were limited to one side, and the question came up as to whether or not it was disseminated sclerosis, which, at the first examination, we were unable to decide.

About a week ago Dr. Bronner asked me to see a patient at the City Hospital, who had been admitted for retention of urine. Under the ordinary treatment, which the doctor administered, the retention was relieved, and he was able to pass his urine very nicely. However, he had a distinct ataxic gait; he gave a history of sunstroke about 17 years ago, followed by epilepsy from which he is still suffering. About five years ago he was injured in a street-car accident, and since that time he has been suffering with this

ataxic gait. He had markedly exaggerated knee-jerk, but the ankle reflexes were normal, Babinski's sign was not present, nor were any of the other reflexes exaggerated. On the second day when I went in to see him, I took him into a private room to examine him, and he said: "Doctor, if it will help you any, look at this sore," and he showed me one of the nastiest looking places I have seen in a long time. He had evidently had a fistula there for fifteen years. Now, this might explain the knee-jerk; it might explain, to some extent, his attacks of retention from time to time; in fact, it might explain many of the symptoms resembling multiple sclerosis. Unfortunately, he left the hospital, and I have not been able to see any more of him.

A. L. C. Perceful: I would like to ask Dr. Askenstedt whether, in his opinion, the periodical or continued use of alcoholics would have any bearing upon the cause of this condition?

F. C. Askenstedt, (Closing): I wish particularly to thank Dr. Pope for presenting these specimens; they have been valuable in illustrating the pathology of this disease.

Reference has been made to the cause of disseminated sclerosis, and Dr. Pope mentioned the theory that infectious diseases are frequently the cause. In this case, however, I cannot trace it to an infection. The patient said he was rheumatic, but you all know what people call rheumatism. Some years ago I had a case that had been diagnosed "rheumatism" by some physician. This was in a colored woman, and it was a typical case of disseminated sclerosis. The pains shifting from place to place give rise to the suspicion of rheumatism. I cannot trace it to any particular disease. He has been a very moderate user of alcohol. Syphilis is not considered a cause. At any rate, this man denies a specific history and I have not found any evidence of it upon physical examination. The only thing that might be considered a causative factor in this case is exposure to cold and dampness. I mentioned in the report that he has been employed in the refrigerating rooms of a large hotel for years, and previous to that he had a restaurant of his own for a number of years. Oppenheimer mentions chilling of the surface in connection with violent emotions, such as is produced by running out on the street from a fire, as a possible cause, and possibly that is the explanation of the trouble in this case, but of course, there must always be an hereditary predisposition to this disorder for any immediate cause to be operative.

I was very cautious in making the diagnosis in this case, simply because I could not get tremor. At times it would seem to be present and at other times absent, and apparently was confined to the right arm. I also stated that his trouble was confined to the right side, and I thought possibly he might have a syphilitic lesion. A cerebellar lesion is supposed to produce nearly all of these symptoms. In cerebellar atrophy we have

ataxia, vertigo, occasional unintentional tremor, eye symptoms, and a few cases are reported that were supposed to have developed increased reflexes. Multiple encephalomalacia also presents a symptomatology almost identical, at times, with that of disseminated sclerosis. Here the pathology is softening of the brain through thrombi forming in the arteries, causing infarcts and consequent softening, so that we have plaques of degeneration instead of induration, and of course, the symptomatology would be very similar, depending upon the parts involved.

As Dr. Moren has stated, the disease is known to be more frequent in Europe than in America; the difference, however, is not so very great—perhaps twice as many in Europe as here. Also, it is more frequent in the East than in the Central States.

I said nothing about treatment in the report, but I will tell you what I gave this man. I administered homeopathic remedies. Mercury and sulphur were the chief drugs used. He says he is stronger and feels better, but I have not made a physical examination since last October, and I do not know whether there has been any improvement or not. Furthermore, I cannot say that any improvement that may have occurred is due to the treatment he has received, because we know that all of these cases show remarkable remissions at times. Therefore, I am not able to offer any opinion as to the value of the treatment in these cases.

HAEMOPHILIA; REPORT OF CASE.

By H. A. DAVIDSON, Louisville,

Dora Adams, white, age 16, a ward of the Kentucky Children's Home Society, came originally from Clay County, Kentucky.

FAMILY HISTORY.

Father living, whereabouts unknown. He is not supposed to be a bleeder. Mother dead, age 45. Cause of death unknown. She was not a bleeder as far as the patient knows. Patient's grandmother, on her mother's side, was a bleeder and died as the result of hemorrhage. Aunt, on mother's side, was also a bleeder and died of hemorrhage; also a cousin on her mother's side, a girl, was a bleeder and died of hemorrhage.

PERSONAL HISTORY.

She had measles and chicken-pox in childhood. Two years ago she had her first hemorrhage from the ears, since then has had bleeding from the eyes, nose, mouth and from cuts, frequently. Three years ago she had her first menses. Her menstrual periods are somewhat irregular, 6 and 7 weeks apart; flow lasts two days, is scanty. Hemorrhage from the other parts of the body are usually worse before menses appear. She had tonsillitis last sum-

mer and bled profusely from her tonsils. She had lobar pneumonia, in the right upper lobe, about three weeks ago. No rheumatic history. She expectorated, freely, prune juice sputum, she also bled from her nose once during the attack. She was given one c. c. pneumococcus vaccine and had her crisis within 36 hours after the injection, it being between the fifth and sixth day of the pneumonia. At various times during the last year she has had attacks of nausea and vomiting. Her heart is irregular. It is enlarged to the right. Pulse rate this morning was 42, temperature normal. She is nervous, irritable and worries a great deal about her condition. At various times she has had calcium chloride in full doses, also calcium lactate in full doses for a long period, also syrup iodide of iron, but these seem to have no effect upon her hemorrhages. On March 4, 1912, I injected 15 c.c. sterile horse serum. She bled for about two days from the point of injection of the serum, there being a constant slight oozing; since that time her hemorrhages have not been so frequent.

URINE ANALYSIS.

Sp. gr. 1020, reaction acid, no albumen, no sugar. Her bowels regular, sleeps well, appetite good, in other ways seems to be in good health.

Through the kindness of Dr. E. S. Allen, of the Louisville Research Laboratory, I am able to submit the blood examination, which is as follows:

Haemoglobin 70 per cent.; Red cells in cu. mm. 4,800,000; white cells 9,800; erythrocytes pale; erythroblasts, few; mononuclears, 26; transitionals, 2; neutrophils, 68; eosinophiles, 4; basophiles, 2; blood platelets, numerous; parasites, bacteria, none.

Clotting time—3 minutes 6 seconds; after extracting several drops there was an entire failure to clot.

Haemophilia has been termed by Grandier the most hereditary of the hereditary diseases. Many theories as to the cause of haemophilia have been brought forth. That of Sahli is probably more in accord with the facts. He believes that haemophilia is due to a chemical alteration in the walls of the blood vessels, and is a disturbance of their functions and not of their morphology. Morowitz has shown that fibrin ferment is formed by the union of thrombogen and thrombokinase in the presence of calcium. In haemophilia the secretion of the vessel wall is entirely inhibited or reduced to a minimum, hence clotting in the mouths of the cut vessels does not occur, as that depends chiefly upon the function of the wall of the blood vessel in pouring out thrombokinase. A case of haemophilia is of importance when considered from the standpoint of Eugenics. No bleeder, especially fe-

male bleeder, should ever be allowed to marry, because it is almost certain to reappear in her offspring.

DISCUSSION:

M. L. Ravitch: I have seen two cases very similar to the one reported by Dr. Davidson. One was a Sister at the Sacred Heart Academy, who developed an eczematous condition of the extremities. This was a case of Dr. O'Connor's. External treatment was applied to the patches without any results. They began to bleed and this aroused his suspicion and he referred the case to me. I treated her for a while and she went from bad to worse. She developed rough erythematous and eczematous patches all over the feet, which bled profusely. Then her eyes became affected and she also had bleeding from the ear. Then she had mouth symptoms, and later developed a condition of the throat that looked just like diphtheritic patches. Her temperature was about 104, and she was given up to die. A very severe pain developed in the intestine, and for a while it looked as if she had appendicitis. Dr. Abell was asked to see the case if it was an operable one, but because she was an haemophilic he did not operate, and we were at a loss what to do. Finally we gave her an injection of 5,000 units of horse serum. Her temperature went down and she improved rapidly, but we would not give her a second injection for fear of anaphylaxis, because all of these patients, particularly those that have purpura, have a peculiar tendency to anaphylaxis and very serious symptoms are liable to result from a second injection. I have had two experiences along this line and I do not want any more. Moreover, a second dose is apt to produce a choking sensation, and may suffocate the patient.

Calcium lactate, if it is given, should be administered in not less than 25 grains at a dose. To my mind a solution of adrenalin, with unguentum and bicarbonate of soda is far superior to calcium lactate.

Ben Carlos Frazier: I had very unique experience, two or three years ago, that I think is worth while to report. I delivered a primipara, after a long tedious labor, of a well developed 9 pound male child, but with quite a large caput. As is my custom, I did not pay much attention to it for a few days, but it seemed to grow larger and was noticed to fluctuate. Therefore, I concluded to open it, which I did and drained off quite a little fluid. A compress was applied and I left. I had not been gone long until the nurse called me back, saying that the child was bleeding profusely. Fortunately, an unusually intelligent nurse was in attendance, and when I got there I found that she had taken off the bandage, placed her finger on the incision and controlled the hemorrhage entirely. Then I began to make inquiries, and learned that this child's grandmother had twice come near bleeding to

death, and that two uncles of the mother had died of nose-bleed.

I am sure that I will never open another caput without first inquiring into the family history.

Henry E. Tuley: I have had no experience in cases of this kind, but I would refer Dr. Davidson to two articles in the March number of the American Journal of Obstetrics and Diseases of Women, relative to the use of human blood serum in melena neonatorum and in cases of haemophilia. In these cases repeated injections of human serum were given, even to infants, with remarkable results.

H. A. Davidson, (Closing): There is one interesting feature of this case that I neglected to mention in the report. When the bleeding from this girl's eyes was first noticed, she was sent to Dr. Lederman, who does the eye, ear, nose and throat work for the Home, and he did not seem to think that such a thing was possible. It seemed that she could have a hemorrhage at almost any time before the serum was given. She had a hemorrhage while in Dr. Lederman's office, and he examined her eyes but could not tell where the blood was coming from. It seemed to come from the conjunctiva, but he could not say just where. He mentioned it to Dr. Ray, who also saw the hemorrhage and could not tell where it came from. I thought possibly at times she would rub her eyes and irritate them, but she denied doing so and said that they just began oozing. At any time she became a little excited, or exercised vigorously, she could start a hemorrhage from the eye, ear, nose or throat.

SEVERE CHOREA IN A CHILD UNDER FOUR YEARS OF AGE; REPORT OF CASE WITH EXHIBITION OF PATIENT.

By D. Y. KEITH, Louisville.

Master A. M., age three years ten months. Admitted to the Children's Free Hospital March 22, 1912, with the following history: Mother living in good health, father living, physical condition good, except some impairment of eyes. One sister living, nine years of age, health good. Has four brothers or sisters dead, causes indefinite; all died under two years of age, one under six months old. They were older than living sister. No history of any miscarriages or of a specific history in mother. No chorea or neurosis on either side of family-tree.

PAST HISTORY.

Has had none of the diseases of childhood, always very healthy.

PRESENT HISTORY.

Four or five weeks ago began with involuntary twitchings of the upper extremities grad-

nally increasing in severity until at the present time they are practically continuous. Three weeks ago leg became involved, first showing as a clumsy gait then staggering as if drunk; now he is unable to stand or walk. Bed covering had to be pinned together to keep little patient covered as well as to keep him from falling out of bed on account of the severe involuntary purposeless movements.

Physical examination revealed a well nourished boy, a distinct blonde. Purposeless movements involved muscles of entire body except the face. Muscles of respiration were involved though there was no crowing as is sometimes seen when larynx is involved.

Visible mucous membrane anemic; mouth and tongue very foul, sordes on lips and tongue, discharging right middle ear.

Patient would answer "yes" or "no" to questions but mentality seemed duller; all voluntary acts were very much delayed. Mucous membrane of prepuce tightly adherent to glans penis, which I was unable to correct completely.

Marked infection around the prepuce and glans penis.

Chest examination negative except few large rales in tracheae and large bronchi. No abnormal sounds were detected on heart examination.

TREATMENT.

Rest in bed under good hygienic surroundings, select diet, repeated cleansing of mouth, middle ear and penis.

Medical treatment consisted of Fowler's solution in increasing doses, hexamethylenamine for middle ear, laxatives and few small doses of morphine to obtain a little rest.

REMARKS.

The only attributable cause that I could ascertain was that during Xmas and many times afterwards patient was scared by a false-face of Santa Claus. Also the marked adhesions of prepuce to glans penis as a reflex cause. Patient gave history of "bed wetting" which has been relieved during stay at the hospital.

I attribute the rapid improvement as seen here to-night to the good nursing, being taken away from home surroundings, absolute rest, overcoming the infection around penis in connection with the large doses of Fowler's solution, minus eight being given at a dose for a few days.

DISCUSSION.

Jethra Hancock: I saw this child with Dr. Keith, and it struck me as one of the most interesting cases I have ever seen. The helplessness of the child was exceedingly pitiable. He could not maintain his head in an erect position

without assistance; all of his muscles were apparently relaxed. He gave one the impression of a chicken with "limber-neck." At that time it seemed to me that he had some acute infection, but it was very indefinite. I saw him again two days ago, and the improvement he has made since I first saw him is indeed surprising; it has been even more radical than Dr. Keith's report would lead us to believe. If medication has brought this about, it is certainly a triumph of therapeutics about which I have heretofore been very skeptical.

Carl Weidner, Sr.: This case is remarkable in that the child has made such rapid improvement. From Dr. Keith's description, the condition must have been very severe.

I have under observation a child a few years older than this one. We do see it in children; we see a good many children with choreiform conditions due to various reflex disturbances—possibly from the eye, the ear, or the nose. I think the eye men could tell us something about these cases. In this child, however, the condition seems to belong to the group classified as chorea major.

The doctor did not say anything about a history of rheumatism. We know that this condition is very often associated with, or follows, rheumatism. I could hear no murmur, or any abnormal sound about the child's heart.

Many years ago I saw a good many children with adherent prepuces, which undoubtedly gives rise to many reflex disturbances in children. I have seen choreic movements in these children, but whether they were due to the condition of the prepuce could not be determined. Most cases that I have seen have given a history of rheumatism.

I would sanction the treatment given by the doctor, which is recommended by most authorities; that is, full doses of Fowler's solution.

One important point in the treatment of this condition in older children is to keep them isolated and not allow them to associate with other children at school, etc., because the other children will imitate them, and not infrequently it will occur in those children. They imitate the movements, and sometimes they keep them up and, as a consequence, become choreic themselves.

Ben Carlos Frazier: I do not believe the arsenic helped this child. In my opinion, it was a reflex condition entirely due to the condition described by the doctor, the correction of which has brought about this wonderful improvement.

W. C. Dugan: Dr. Frazier has expressed my views exactly; the improvement in this child is due to correction of the penile condition. I remember the case of a child that had been circumcised, and the mucous membrane left which fitted over the end of the penis like a kid glove. When I was called to see this child, he had

chorea minor. While walking across the floor he would jump up on his toes and remain in that position. The mother thought the child was paralyzed. When I asked her to take off the child's clothes, she said, "Doctor, there is nothing wrong there; he has been circumcised." Nevertheless, I insisted upon examining his penis, and found the condition I have described, which was corrected and the child's chorea was entirely relieved.

I agree with Dr. Frazier that arsenic had nothing to do with the improvement in this case.

M. L. Ravitch: It has been a long time since I treated these affections, but I remember that arsenic seemed to help the condition very much.

Too much arsenic is given in these cases. Many cases of eczema have been caused by giving too much arsenic. The average practitioner gives arsenic without any caution. They should be very careful in its use because many skin troubles such as keratosis, and even cancer, have been caused by giving too much arsenic.

David C. Morton: Dr. Weidner brought out one point that is very essential in the treatment of these children. Whether it be arsenic, or rest, or education, or what-not, that brings about improvement, the best results are obtained by isolating the patient to a certain extent. I recall a case that I had, in a boy, twelve years of age, who had a chorea of the minor type, and had to be kept away from school practically all of the time. This boy's mother was constantly nagging at him, from morning to night; she scolded him for the most trivial things. He was sent on a camping trip with some other boys of the same age, and there was immediate improvement, which the mother attributed to the fresh-air, living out of doors, etc., which, of course, had a good deal to do with it, but in my own mind I attributed his improvement largely to freedom from the everlasting nagging that he got at home. This is a point that should not be forgotten in the treatment of the functional nervous troubles of childhood.

D. Y. Keith, (Closing): I wish to thank the gentlemen for their generous discussion of this case.

Just a word in regard to chorea major. Dana says that chorea major is a manifestation of hysteria, and he describes it under that head. He further says: "It is not a chorea at all."

I am sure that isolation has been worth a great deal in this case, as well as attention and rest.

In regard to the correction of the penis condition, nothing was done in an operative way. It was simply cleansed and the prepuce retracted daily until we got rid of the infection. He had marked adhesions around the prepuce and some of them are still there. The infection of the prepuce has been entirely relieved.

I have never been able to detect any irregularity of the heart. The text-books all speak of

choreic movements of the heart muscles, but I have listened to his heart with the stethoscope many times and have never been able to detect any such movements.

DELIRIUM TREMENS FROM PARALDEHYDE; REPORT OF CASE.

By MILTON BOARD, Louisville.

Paraldehyde is a polymeric form of ethylic aldehyde. It is a byproduct of alcohol or vinegar obtained by the action of an oxidizing agent like chromic acid. It is a colorless transparent liquid having a strong characteristic but not unpleasant or pungent odor and a burning and cooling taste. When cooled to 32 degrees F., it solidifies to a crystalline mass which becomes liquid again at 51 degrees F. It is miscible with alcohol, ether or oils.

Paraldehyde in doses of 1-2 to 1-2 teaspoonful is a hypnotic having an effect very similar to chloral for which it was offered as a safe substitute. It will not relieve pain but is irritating to the mucous membrane and impairs digestion.

Large doses are attended with great prostration, low muttering delirium and death may occur from paralysis of the respiratory center. Its prolonged use, according to Dr. J. G. Kearnan, is followed by nasal ulcers, skin eruptions and other evidence of impaired nutrition. Very few cases of the paraldehyde habit have been reported though Kraft-Ebing has called attention to the habit and Crothers mentions it in his work on narcomania. In my experience of more than 8 years in special practice I have had but one patient addicted to this drug whose case I report as follows. Patient, J. H. L., age 35, single, occupation a country school teacher. Was admitted to my institution on July 19th, 1911. Patient came in drunken from the effects of paraldehyde, had fallen on the street and presented the general appearance of an acute alcoholic though he had taken no whiskey. He gave the following history:

Some three years before he had consulted a physician for some nervous trouble with insomnia and was given a prescription of paraldehyde with some liquid preparation of pepsin, this he continued to have refilled and to take in increasing doses and more frequent intervals until he became a paraldehyde drunkard.

Patient was emaciated, highly nervous, and showed the general effects of persistent poisoning. I withdrew the paraldehyde at once and gave patient strychnine hypodermatically and trional and sulphonal at night. Violent delirium ensued with the appearance of animals coming on within a day or two and lasting ten days. During this time patient was given hot baths frequently, sedatives be-

ing used very moderately. Patient was supported with strychnine and systematic feeding. When the delirium subsided a course of iron tonics with cod liver oil was given.

Patient went home at the end of a month, eating well and sleeping naturally.

I report this case because it is rare, and to emphasize what I have often said before, that a safe, reliable hypnotic, which is not habit forming, is the dream of the empirist and the boast of the manufacturing chemist, but in reality does not exist. The great majority of people who become addicted to drugs or alcohol remain so throughout life notwithstanding the numerous "cures" to which they are subjected. Here, as elsewhere, our greatest work is in prevention, and as physicians we should be careful, especially in dealing with neurotics in prescribing an anodyne or hypnotic.

CHOLESTEATOMATA OF THE EAR.

By W. T. BRUNER, Louisville.

The term cholesteatomata is applied generally to a collection of epithelial cells, round or polygonal, arranged in concentric layers and mixed with fat-globules and crystals of cholesterol. Sometimes the whole mass is covered by a pearly, shining membrane.

There is a great difference of opinion among pathologists as to the origin of these masses, some maintaining that a cholesteatomata in the temporal bone is of heteroplastic formation while others consider it to be a retentive tumor. Still others believe these scales to be formed in the external meatus and to extend through a perforation of the drum into the middle ear, and antrum. The mastoid cells seem to be the most frequent seat of the disease. In some cases the cholesteatomata is of small size while in others it is very large, leading to more or less destruction of bone from pressure and absorption, or there may be extensive caries. The middle ear, antrum and mastoid are sometimes transformed into one large cavity.

I report this case for two reasons. First, because there has been a dearth of ear cases reported to this society of late, and second, because the case itself possesses one or two points of unusual interest.

In an extremely limited number of instances this disease has been known to originate primarily, but in the very large majority of cases it occurs as a complicating feature of prolonged suppurative disease of the middle ear and its accessory cavities. This case is one of those rare cases originating independently of any suppurative condition of the middle ear or mastoid as far as can be elicited.

Mrs. H., age 35, white, married. Now in the seventh month of pregnancy. Family

history and personal history negative. I was called by the attending physician on March 16, he having treated her since about the first of March for a furuncle of the ear. I found her suffering excruciating pains in the ear with the ear canal completely occluded by a swelling which looked very much like a furuncle. Examination revealed a tumor covered by a pearly, shining membrane. An operation was advised and accepted. On account of pregnancy existing the operation was performed with cocaine. A free incision was made through the pearly membrane and a great quantity of cheesy material evacuated. The tumor was found to extend as far back as the drum membrane, but the drum was intact. After removing all of the cheesy material the bony canal was found to be carious this was curetted and all of the necrotic bone removed. There has been some suppuration following the operation but it has now about cleared up.

The only plausible explanation, to my mind for the localization and confinement of this mass within the external canal is the probability that this patient had in infancy or early childhood a suppurative middle ear condition with perforation of the drum and as the cholesteatoma developed in the tympanum, it was thrown out into the external canal and there remained, and on account of the irritating qualities of this mixture of pus, epithelial cells and cholesterol, brought about an excessive production and desquamation of epithelial cells, and as the cholesteatomata increased in size the external canal gradually became filled with the accumulation and by pressure the bony walls began to soften and break down.

The drum membrane in this case has a cloudy and thickened appearance, and its markings are dim and uncertain.

DISCUSSION.

Adolph O. Fängst: This is quite an interesting case, and I think both the patient and the doctor are to be congratulated. It appears that this was a case of spontaneous operation, without the aid of a surgeon. This sometimes occurs in these cases. It seems that by pressure portions of the bone are cut away, with practically the same result that we secure by doing a radical operation. It is the best thing that could happen for the patient, not only liberating the cholesteatoma, but giving free subsequent drainage, thus obviating the danger of further trouble.

The subject of cholesteatoma has been discussed for years, and there is still quite a diversity of opinion as to the pathology and etiology of this condition. I have seen quite a few cases, and I believe there are two separate and distinct conditions that we call cholesteatoma of the ear. Both of these are characterized by a foul odor

from the canal, exacerbations of pain, some dullness on that side of the head, dizziness, etc. The condition that I have most frequently observed is that in which the middle ear itself, the tympanic cavity and the antrum fill up with masses of tissue, made up of flakes of pus, pus cells, and fibrinous material from foul pus that has been in there for some time and decomposed. The other variety is the one just mentioned by Dr. Bruner, where the epithelial cells are in concentric layers. He said the cells are round, but he meant that they are discs; they are flat, squamous cells, and not oval or round. These come either from the tympanic cavity or from the ear canal itself, and here is where a diversity of opinion exists. Some schools (that of Virchow for example) believe that cholesteatomata are simply desquamated epithelial cells from the skin of the ear canal, and do not form unless there has at some time been a perforation of the drum membrane, allowing these epithelial cells to invade the tympanic cavity. Others believe that they are endotheial in origin, such as are found in the soft parts elsewhere in the brain. Favoring the argument that they come from the skin, the fact is cited that we do not find this condition in the frontal sinus, for instance, which is lined with mucous membrane instead of skin. Still others believe that cholesteatomata arise in the tympanic cavity itself, and offer as an argument in favor of this theory, that we find cholesteatomata as a primary trouble, where there is no history of a discharging ear. In the case reported by Dr. Bruner, the history of a discharging ear is very vague, and some cases are cited where it was pretty certain that there had been no discharge from the ear, and still cholesteatomata were were found.

An interesting feature of this condition is its treatment. These cases are all serious, I think, because there are very few instances of spontaneous cure, such as occurred in Dr. Bruner's case. On the other hand, many of them are apt to be followed by serious results on account of the pressure. These flakes are sometimes as large as a pigeon's egg. They are of concentric formation, one layer of epithelial cells forming on top of another, just like an onion, and under the pressure the bone atrophies or rots, and large cavities are formed. The danger here lies in the possible erosion of a blood vessel, or the meninges, causing meningitis, or cutting into the sinuses, or even into the arteries. There is only one method of treatment, unless spontaneous cure takes place, and that is radical mastoid operation. If there is a large opening, so that we can keep the cavities cleaned out, there is no use in doing an operation, but where there is only a very small passage-way the cholesteatomata will reform, and while we are waiting for it to do that, more damage may occur. It is not a malignant growth in any sense of the word, but it will re-

cur unless there is a free opening and it is exposed to the atmosphere.

Ben Carlos Frazier: Are cholesteatomata frequently seen in children?

Adolph O. Pfingst: I do not know the exact percentages, but I think it is far more frequent in children than in adults.

B. C. Frazier: I have seen three or four cases of this kind in connection with mastoid operations, and the reason I asked Dr. Pfingst this question was because I have only seen or heard of one case in a child, and I was under the impression that it was quite rare in children. I remember hearing a case that Dr. Pfingst reported to the society, as well as one or two others, and I thought the condition always occurred in connection with mastoid diseases. I am glad to know that this is not always the case; that it may occur without mastoid involvement.

W. T. Bruner, (Closing): The particular point of interest in this case, to me, was the fact that I was unable to get a history of any ear trouble. I questioned the woman very closely, and she denied ever having had any ear trouble of any character. However, the history given by the average patient in regard to ear trouble cannot be relied upon, because many children have suppuration of the middle ear when they are too young to remember it; they apparently get well and never know that they had ear trouble. It is my opinion that this woman had middle ear disease when she was a very young child and does not remember it, and that this condition developed from it.

These growths will go along for years and years and never cause any trouble until the bony structures begin to break down, or until the ear canal becomes occluded, when the pressure will give rise to pain.

I was hoping that some one in the discussion of this case would give us a little more light upon the origin of this condition. I do not know much about it nor can I learn much from the literature I have been able to search. It seems that it is not definitely known just how this condition originates.

REPORT OF CASES.

By M. L. RAVITCH, Louisville.

CASE I.—ERYTHEMA CALORICUM.

Mr. E. W. W., age 29. Last December he was burned by explosion of gas, about the face, scalp and both hands. As the accident occurred in a little village, the patient received very poor attention. The burned parts were covered with absorbent cotton. Later he was removed to town and the cotton had to be pulled off. The parts were washed with antiseptics. Bullae formed in many places. Salve was used, perhaps unguentine. After six weeks, the patient was able to go about.

The erythema caloricum, as a sequel to the burn, began to give him trouble. Pruritus

was the chief symptom, at times it was accompanied with burning and pricking sensations.

Several weeks ago the patient developed erysipelas. It lasted two weeks. It neither aggravated nor improved his condition. Pruritus with occasional pustulation still continues. Pruritus is likely due to atrophic changes which took place in cutaneous tissue, perhaps to gradual disappearance of the papillae, as you see in senile skins.

Can something be done to improve his condition? The pruritus, perhaps, can be overcome, but the cosmetic condition, I think, will not improve.

CASE II.—AN UNUSUAL CASE OF VERUCCA ACUMINATA OF THE MOUTH.

Mr. A. V., age 74, came to me a year ago complaining of a sore mouth. Upon examination I found he was suffering from an innumerable amount of moist warts or verucca acuminata. Chemical cauterizing and astringent lotions have greatly improved his condition. Later on he failed to treat himself as he was directed, and some of the warts assumed a very bad aspect. Some of them have coalesced and are becoming degenerated. It seems to me that in this instance, the irritant that produced the condition is a microbic one.

Microscopical examination showed marked papillary enlargement, excessive proliferation of the rete. This kind of warts do not show any tendency to disappearance and are undergoing cancerous degeneration.

Stronger remedies will have to be resorted to to remove these growths.

OPERATION FOR TRAUMATIC EPILEPSY.

(PRESENTATION OF PATIENT AND REPORT OF CASE.)

By CHALLOM GUY FORSEE, Louisville.

Patient, Mr. S., age 45; American born; married; three children living and four dead; youngest living child 14 years of age. Father and mother living and in good health; brother and sister living and in good health. One sister died of typhoid at the age of 19.

Some time in 1899 or 1900, during the winter, while at work, he struck his head against a projecting timber; was not knocked down but felt very sick. He was seen by a physician who gave him large doses of morphine to control the pain. However, pain in the head and face continued, and was so severe at times that he would become violent. On one occasion, which was in the winter time, he got out of bed in his night clothes and went several squares before he was overtaken and

brought home. Thirteen weeks after the accident he went to Dr. Holloway, who examined him, and referred him to a dentist for examination of his teeth, as he was suffering great pain in the head, teeth and jaw. The dentists reported his teeth all right and sent him back to Dr. Holloway. A few weeks after the accident he began having fits, and at the time he was referred to the dentist he was having them frequently, suffering a great deal of pain in the intervals. Dr. Holloway advised operation, which was done and only a scalp wound and no fracture was found. After this operation he was free from pain and had no fits for three years. After that the attacks returned, first at intervals of six months, and becoming more frequent until, at the time of the second operation, he was having on an average of one a day. Dr. W. O. Roberts trephined the skull and removed a button about half an inch in diameter, the dura being adherent to the button removed. He was relieved by this operation until about one year ago, when he began having the same trouble again, and the attacks soon became as frequent as before. I operated upon him February 12th, 1912, simply removing the scar tissue, which was adherent to the dura, and enlarging the trephine opening. Since the operation he has had two attacks, but he tells me that, following the previous operations he suffered a few attacks. He sometimes has what he calls a burning, stabbing pain in the right side of the head, and occasionally he has to stop work and go home. He has been working steadily since the operation.

I will say that, at the time I operated on him, he had started from the factory where he is employed, to go home, and fell on the street. He was taken to the Infirmary where I saw him and operated.

DISCUSSION.

Wm. A. Keller: I would like to ask Dr. Forsee if he operated through the site of the original injury?

Jno. J. Moren: I would like to ask Dr. Forsee what is his prognosis as to the continuance of these attacks?

C. G. Forsee, (Closing): I will say that the first operation was done directly over the site of the injury, and subsequent operations have been in the same scar tissue.

As to Dr. Moren's question, I think he will probably have a recurrence of these attacks from the history he has given.

REPORT OF SURGICAL CASES.

By IRVIN ABELL, Louisville.

CASE I.—RENAL TUBERCULOSIS.

This specimen was removed from a patient first coming under my care on February 21st, last, having been referred to me by Dr. John Broderick, of Lebanon. Her history is as follows:

Mrs. J. R. S., Lebanon, Ky., age 27. Father living, age 64, mother dead, tuberculosis; seven brothers living, one dead, tuberculosis; three sisters living, one dead, tuberculosis; disease and one with tuberculosis; married seven years, no children, three miscarriages at third month, the last one three years ago. No severe illness since childhood until the inception of present trouble.

PRESENT HISTORY.

In 1904 had an illness diagnosed as "gravel," pain in abdomen, painful and frequent urination: in 1905 passed at one time several small gravel (calculi). Free from pain thereafter. In September 1908 she noted frequent and painful urination, with pain in left side of abdomen: this has continued more or less constantly since, at times more marked than at others: pain in side such as to prevent rest at times and when severe is associated with desire to micturate and intense straining. Frequency of urination more marked when on feet, averaging every two hours during day and ordinarily one or two times at night, occasionally frequency greater at night. Blood never visible to eye of urine. No marked loss of weight. Examination of urine showed a specific gravity of 1013, acid, color, amber; cloudy, albumin present, sugar absent, blood present, pus present, epithelium vesical and renal, uric acid crystals, small hyaline cast.

EXAMINATION.

Patient's general appearance seemed fairly good and she stated that her weight and color to be about her normal. Examination of lungs failed to reveal anything abnormal; examination by circulatory apparatus showed blood pressure of 150, pulse 80, heart sounds normal; examination of abdomen revealed a mass in the left side corresponding to the lower pole of kidney which was very sensitive extending downward over the course of the ureters. Muscular rigidity was found and pain on pressure was noted. Cystoscopy was done under cocaine: bladder mucosa healthy except around the left ureter orifice; this was congested, pointing with oedematous granular appearance. A nodular enlargement along the course of the ureter could be seen under the bladder mucosa; the right ureteral orifice normal. A number six ureteral catheter

was easily introduced into the right ureter as far as the pelvis of the kidney; the catheter would enter the left ureter only for a distance of one inch. Consequently, the left ureter urine was collected from the bladder by means of a Nelaton soft rubber catheter while the right ureter catheter was in situ. Analysis of urine from the right ureter showed the following: transparency clear, reaction acid, specific gravity 1008, urea 8 per cent., uric acid none, total solids 21 grams—1000 c.c., albumin serum trace. Cells: cystic none, renal none, an occasional leucocyte, blood present, round and caudate cells. Casts none. Cylindroids none, shreds none, crystals none, urates present, bacteria an occasional colon. The analysis of the left ureter showed the following: transparency cloudy, reaction acid, specific gravity 1005, urea 5 per cent, uric acid a few crystals, total solids 13 grams—1000 c.c., albumin trace nucleos, haemoglobin present. Cells: few cystic, small round renal, quite a number pus, blood abundant, bladder. Casts: few small hyaline. Bacteria: numerous colon, tubercle bacilli. The phenol-sulphone-phthalein test for renal efficiency gave the following results: appeared in the right kidney urine in 28 minutes and the left kidney urine 30 minutes, the right kidney urine showed 25 per cent. of the drug, the left kidney urine 15 per cent of the drug in one hour's collection. She was operated on at St. Joseph's Infirmary on February 29th, last. Left kidney exposed by oblique incision which was carried one and one-half inches below the anterior superior spine of the ilium. The kidney, which was large and lobulated, separated from its surrounding structures; the arteries and veins of pedicle ligated with silk, the ends being left long; the ureter was then bared to a point below the pelvic brim and ligated with catgut. A rubber drainage tube was carried from ureter stump through the wound and brought out the stab puncture with the silk ligatures and cigarette drain, stab being situated behind the upper angle of the incision. The wound was then closed with sutures of silkworm gut and continuous sutures of chromic catgut.

POST-OPERATIVE HISTORY.

Very little discomfort and remarkably little reaction was experienced from the operation. The wound on account of drainage required frequent dressing; the cigarette drain was removed at the end of a week, the tube at the end of ten days and the ligatures of kidney pedicle and silkworm gut sutures on the fourteenth day. The wound healed, except at point of drainage, by first intention. At the end of the first week bladder frequency became less and at the time patient was discharged from hospital on the twenty-fourth

day, she was able to retain urine from three to six hours. At this time urine still showed the presence of some pus.

CASE II.—SARCOMA OF THE KIDNEY.

This specimen was removed from a woman, 63 years of age. Practically all of her family except herself are dead. The family history, is without interest except that one sister suffered hemorrhages between the ages of 10 and 20, dying at the age of 20.

Present trouble began in August, 1911, when she noticed clots of blood in the urine over a period of one week. She says that the urine was not colored red but contained a number of clots, and at the end of a week she was greatly exhausted from what she took to be loss of blood. During this period tenesmus was marked, accompanied by considerable back-ache, and she was confined to bed for a week. No pain on urination. Subsequent to that time, she suffered attacks of colic in the abdomen, always accompanied by an intense desire to micturate. These lasted about one day, as a rule. Commencing in September, 1911, there has been a constant loss of weight. She weighed at that time 212 pounds, and when she came under my observation her weight had decreased to 168 pounds. During this time no pain was noted, but a constantly increasing weakness. In February, 1912, a mass was noted in the abdomen on the left side. This constantly increased in size, but was never painful, even on pressure. However, she complained a great deal of pain in the left leg, and during the last two months she suffered considerably from intestinal disturbance.

Blood examination showed: Haemoglobin, 65 per cent; red cells, 4,800,000; white cells, 8,000; lymphocytes greatly increased. With that exception, the white cells were apparently perfectly normal. The urine showed nothing abnormal except the occasional presence of leukocytes.

Catheterization was not done by me but by Dr. C. Wheeler, of Lexington. He reported nothing abnormal in either the right or left ureter urine; that the left ureter urine was nothing more nor less than water.

The tumor which we removed, and which I herewith present, illustrates a point that was brought out in the discussion of a paper here a short time ago, on the subject of malignancy; that is, I think it is well, in such cases, to examine for possible secondary deposits before removing the original growth. My diagnosis in this case was a malignant growth of the kidney. Accordingly, a primary incision was made in the left semilunar line, and the abdominal viscera examined for secondary deposits, but we were unable to find any. Consequently, the primary in-

cision was closed, a left lumbar incision made and this growth removed. Microscopical examination shows it to be a round-celled sarcoma of the kidney.

DISCUSSION.

B. J. O'Connor: I cannot add anything to what has been said in regard to the pathology or symptomatology of renal tuberculosis. The symptoms of this condition are frequently overlooked by the patient until the disease has reached a stage where surgery is of no avail. I have seen two cases of that kind, in which there was involvement of both kidneys as well as the bladder. Pulmonary tuberculosis was present in both cases, and operation was refused. In the first case, after four months rest in bed, the patient was able to get up and go about. Four years have now elapsed and the patient has had no symptoms of the trouble in that time. In the other case, which I saw about two years ago, the same line of treatment was carried out. During the first six months the amount of pus in the urine gradually decreased, and to-day it contains practically none. While the symptoms are still more or less marked, the condition has greatly improved, and the patient's general health has also improved.

In a great many cases of renal tuberculosis, the abscess cavities or the tubercles themselves, will undergo calcification. Of course, the kidney substance is more or less destroyed, but there is possibly hypertrophy of the remaining healthy kidney tissue.

The question of tuberculin treatment in these cases is a very interesting one. A great many authorities advocate tuberculin treatment, and I presume that, in selected cases, a great deal of benefit may be derived therefrom.

APPENDICITIS.

(REPORT OF CASES.)

By M. CASPER, Louisville.

CASE I.

Mr. F. N., age 50; developed severe cramps with vomiting and purging following the eating of fish. The physician in attendance had cogent reason for thinking it ptomaine poisoning, as patient gave a history of attacks of so-called "acute indigestion" with frequent attacks of colic followed and relieved by vomiting. These spells always developed after eating a cold lunch at a railroad lunch counter, he being a passenger conductor. This was Friday and these symptoms continued two or three days with first abatement of pain then increase, which phenomena may have resulted from the indiscriminate use of morphia administered at irregular intervals.

I saw patient Monday after physician in attendance had made tentative diagnosis of ap-

pendicitis. Patient presented at this time pain of a general abdominal type and no localized tenderness.

Patient referred to pain as seeming to be worse in loin of right side. Temperature 99; pulse 120; tongue coated; bowels now constipated. Patient felt improved—much improved—and was hungry. His greatest discomfort was in urination and his condition might easily be accounted for by impacted renal calculus in right ureter.

It was not a typical case and was decidedly difficult to diagnose. It was harder still to get not only a seemingly improving patient's consent to operation, but the attending physician's as well.

Operation was performed at once; appendix and cecum were both gangrenous; free pus in abdomen and peritonitis fairly well developed with no attempt at walling off. Hasty removal of appendix, and gangrenous part of cecum removed and inverted, followed by profuse packing and drainage. Ultimate result looked bad, but patient finally recovered after stormy and prolonged convalescence. Tympany was great and lasted two weeks without abating and probably this extensive tympany prevented fatal spread of the peritonitis. Proctoeclysis and Fowler position used; latter kept up for two weeks; in fact patient did badly whenever we resumed horizontal position or any approach to it. An ugly decubital ulcer followed the prolonged Fowler's position and showed to what extent patient's vitality was reduced.

CASE II.

Miss C., school girl; age 16 had never had any complaint of similar or even referable type before. However, she was pale and delicate, and mother remarked always sickly since 4 years old and now had a Bell's palsy.

Was stricken ill Sunday night but not severely and had cramps in abdomen that night and Monday with some nausea and constipation. Still patient was not considered very sick and no doctor was consulted until late Tuesday afternoon.

Diagnosis was made and patient sent to hospital. Patient was no better Wednesday morning. Temperature 99-102; pulse 120; and facial expression indicated more trouble than any other symptom and it was on this that immediate operation was decided.

This case seemed so mild that I was greatly surprised to find a gangrenous appendix and a piece of cecum as big as a dollar gangrenous, and ready to drop out, while the rest of cecum was covered with fibrous exudate. Treatment same as other case but recovery was prompt and uneventful in this case.

CASE III.

Miss H., age 26; stenographer; became ill on Sunday before Christmas with severe colic, which was thought to be a spell like others that she had had. Doctor called and gave a hypodermic of morphia, thinking it indigestion. I saw her Monday night at 9 o'clock, found abdominal tenderness, marked in lower abdomen, colicky pains, tympany and constipation. Temperature 100; pulse 100. Diagnosis, appendicitis and localized peritonitis. Operation revealed bound down appendix, with end sloughed out; numerous adhesions, old and recent, and a pair of pus tubes. Recovery prompt and uneventful.

This case exemplifies the importance of always making a vaginal or rectal examination, else any of us may slip up. I had saved myself unwittingly by remarking that case was complicated in this instance. I have come to the conclusion that the best time to operate in appendicitis is as soon as possible after diagnosis is made in all but a few exceptional cases.

We can't see, nor be sure of what is going on on the inside. It so often happens that the mild cases present the worse pathology when we get inside and it is these mild cases that need the most careful scrutiny; the real bad ones guide their own proper procedure.

I wish to protest against the use of morphia in appendicitis which, though generally recognized as bad treatment, is nevertheless too often used. Also to urge the general practitioner to be a little more careful in calling his colic cases indigestion, and very often not giving the proper examination.

Finally, death in appendicitis is always and only fatal delay somewhere and should never occur.

Acromegaly and Hypertrophic Osteo-Arthropathy.—In the first of the cases reported by Schultze and Fischer the patient was a girl of 15 with a hypophysis tumor, acromegaly and partial obesity. The first symptoms had been observed at 11. In a second case the patient, a man of 56, succumbed to hemorrhage from a myoma in the stomach. He had complained of symptoms on the part of the stomach since a contusion of the region seven years before. Then the acromegaly developed and a tumor was found in the hypophysis. The adrenals in both cases were enormously enlarged, all the viscera having grown to unusual size, the adrenals to five times normal. Some other cases are compared with these and the etiology discussed, especially of the benign tumors in the hypophysis.

ACUTE GASTRO-ENTERIC INFECTION*

By W. W. MORTON, Catlettsburg.

In the etiology of this disease, we find that age and thermogenic exhaustion, coupled with improper food and feeding, are the hubs in the etiological wheels of this disease, or condition.

The spoons are filled in with everything that lowers the general vitality, such as foul air, unsanitary surroundings, want of proper care, and ordinary cleanness. (We often find the child upon a dirty rag or quilt on the floor or bed, saturated in its own discharges, flies swarming over and around the child, and the child often too sick to defend itself against their onslaught, and the mother complaining that the child is not doing well and that the medicine is not doing much good. This is not an unusual or rare sight for many of us, and is only drawn upon to remind you that the same care and motherly attention is given to the preparation of their food).

Bacteria, saphoritic and pyogenic are also vital factors. Faulty digestion, weak constitution. The hand-fed, or rather over-fed, suffer the most, for they suffer most of the time from a gastric intestinal catarrh caused by improper food and feeding, and this season of the year the food contains more bacteria and the larder more dangerous and improper foods. The breast-fed are less susceptible on account of better digestion and their food is free from bacteria and bacterial changes.

But the over-heating and swilling of the mother's stomach or the improper or strenuous life on her part, coupled with a taste of this or that at the table and often chewed first for them, thus incorporating what pathogenic bacteria her mouth contains with other improper food will soon leaven the whole lump into a hot-bed of disease. And the common and dangerous practice of nursing or feeding them all the time to keep them from crying, these practices will soon suck the breast-fed into the etiological wheel, but they are not so easily broken up on this wheel as the hand-fed, for if you will clean out their little stomachs and rest them for twenty-four hours, most of the grave symptoms will disappear. Not so with the hand-fed, or over-fed. They will wheel on and on and we will have much to do with them in pathological field later on.

Remember the heat has much to do with the toxemia and the virulence of the pathogenic germs is increased. The excessive heat causing a diversion of the fluids of the body from kidneys to skin, to such an extent that excretion is almost exclusively carried on by the skin, the result of which is that a great amount of the toxic products of excretion are re-

tained in the system. It has been estimated that the sweat glands only eliminate about one-fourth as much as the kidneys. Thus in this disease you have a dangerous proportion of the resulting toxemia that you must get rid of through the bowels and kidneys. You also have a lowering of the blood pressure which, as you know, will further decrease the elimination of toxins.

And last but not least, on account of the enormous loss and diversion of fluids you have a flagging heart.

I will now call your attention to the demon of destruction that has been crowned as a harmless associate for the destruction of the innocents, viz: Teething. And why, because they told us so, and we told them so. They told grandma so, and they told grandpa so. That old man "They" is hard to down, but we must run him down to save the little ones.

We must teach grandmothers, grandfathers, cousins and aunts, that they are not only teething but that they are engaged in a mortal combat for their little lives. And we as well must learn to look outside the little dental suck, that only takes the dental pulp a few weeks to dissolve and destroy, for etiological factors and look well into the little stomach and what goes into it, for it is the starting point and the battle ground. So do not forget that in this condition they are not only teething but *sprouting wings*. We have been told, some of us *young fellows*, to lay open wide the little gums. Why? To let in some bacteria, I suppose, that could not enter safely by the old route. We have been told it was an etiological factor and closely associated. They are in this way, for just at this time in childhood, or evolution, there is a very rapid functional activity going on that pre-disposes to gastric as well as intestinal infection. That only takes a little improper food and feeding to fulminate. To illustrate:

Fill a six ounce stomach with twelve ounces of milk and you will have a distention that will arrest digestion. Plus fermentation, giving you a pathologic distention. That strangulates the gastric follicles, jugulates the blood-vessels, weakens and *widens the field of infection*, inhibiting the nervous impulses that preside over the valves of the stomach, thus shutting in this vile mass of putrefaction, until the resulting chemical changes wrought upon the sympathetic nerves, causing them to open wide both valves of the stomach—Nature's safety-valves—through which the vile mass is expelled by vomiting and purging. You have all witnessed this and have been thankful to kind nature for its good results, and you have no doubt, as I have had, great trouble in preventing the anxious friends from again repeating the dose.

We will now take up the pathology.

*Read before the Boyd County Medical Society.

We find a superficial catarrhal condition of the whole gastro-enteric tract which will vary in different cases and regions. The colon, lower ileum and stomach suffer most. Duodenum and jejunum least. The stomach as you would expect, is distended and contains undigested food. Its walls intensely congested in spots, and surface covered with a tenacious mucus. (That arrests and prevents digestion). The condition of intestines are about the same and in them you have the same congestive spotting and in lower portions undigested and very foul and offensive material. Now why do you have this intense congestion and congestive spotting in stomach and in the intestines? They do not tell us—the books. I think that it is due to, or rather they are manifestations of, chemical disintegration, due to the metabolic activities of microorganism engaged in satisfying their nutritional requirements. This poaching upon a suitable soil, made so by the ingesta and the constitutional disturbance, causing the congestive spottings, which might fittingly be compared to burns of first and second degree. 'Tis here in the severe type where it crosses the imaginary line into ilio-colitis or the neuritic form.

SYMPTOMS.

As a rule you have a gradual onset with little or no fever. Child is fretful, cross, especially at night, stools abnormal, mild gastric disturbances. At first they are generally let alone under the impression that they are only *teething*. The child grows pale, limbs or muscles become soft or flabby. They sleep little at a time, lose their spirits, do not want to play, are hard to amuse, lose flesh, and are generally out of sorts and *sick*, bowels giving them trouble. All the symptoms will gradually grow worse. In another type, or the grave form, the child seemingly is in good health. Will suddenly get sick, skin will be hot and dry. Temperature ranging from 102 to 106 degrees, lies in a stupor with sunken eyes, weak pulse, very restless, rolling its head from side to side. May have great thirst grabbing at everything offered, or upon the other hand may refuse everything, vomiting and purging. Vomiting at first food that has been in the stomach for hours, they continue to vomit after stomach is empty on account of action of toxemia on central nervous system. The stools are first fecal with great bursts of flatus. Later the stool only consists of thin green material that is very offensive. They may have from fifteen to twenty stools a day—after a time you will have mucus, epithelial cells, blood, bile, etc.

In the feeble child you may get no reaction from these severe attacks, child only living a few days. This may be explained by the

known fact, viz: that the intestinal secretions taken as a whole, possess very feeble resisting power over bacterial *multiplication*.

The well known fact of the normal presence of bacteria increasing from duodenum to colon, that have and will remain with us until death. Whether they are helpful or not, I do not know. (Schattellias thinks they are), but we do know with a healthy mucosa, a healthy and normal cellular, actively normal peristaltic wave to pass them on and out, we can take care of them and vice versa. And right here let me remind you lest I forget; the bacterial flora are largely due to ingesta.

DIAGNOSIS.

Attacks of intoxication cannot be differentiated from acute indigestion, but it is not essential if you will go after it at once. If you will note carefully the grave nervous symptoms, high temperature, stinking stools, unusual look and restless condition of child, you will want to know if the digestive symptoms are the cause of the fever, or the result of the fever. After flushing out the stomach and bowels you can tell. If due to the former most all the grave symptoms will disappear after this. On the other hand the condition remains grave. You may have convulsions, profound stupor and opisthotonus, etc., simulating meningitis very closely, and other sympathetic phenomena that is very misleading, but do not let them lead you off on a wild goose chase; they are mute signals of the profound toxemia. Fight it out on the original battle ground—the little stomach and bowels. Look well to what goes into them and examine carefully what comes out and you will be well informed as to the internal condition. Do not forget that you will have cases suffering from this disease in which you will have no diarrhoea but an obstinate constipation and in some diarrhoea delayed for twenty-four to thirty-six hours. The toxemia simply paralyzing the peristaltic wave, and you will have great trouble in getting them to move. In the infant vomiting is not so common, but pain—colicky pains—are more common and skin eruptions more frequent. The temperature is of an irregular and intermittent type. That is a malarial climate, and undoubtedly you have them in combination. It would be strange if you did not, but you have the test for malaria and the remedy.

I have not encountered this disease in the winter months, only in some cases of bronchopneumonia. Then I have found it in such a true type that had it been in summer months, I would have overlooked the pneumonia. Why should it be reproduced in such true form in this condition, I do not know, unless it is due to an autoinfection, but why due to this I cannot say. We might class the exist-

ing condition to an etiological factor, like teething, but it would not elucidate matters much.

TREATMENT.

I feel like saying elimination. Plenty of pure, fresh water outside and inside, proper food and surroundings, and letting it go at that. But we all want to know what the other fellow gives, etc., and I take it that is just why we have these meetings to talk it over, exchange views, etc., and thus grow broader and more proficient.

Let your remedies be intelligent and energetic from the start, keeping in mind the fact that the normal balance has been upset, and in severe types you have anatomic changes in the gut, and that absorption of your medicines, as well as your foods, will be difficult. They will select and absorb some, reject others, and pass them on and out through the bowels. This loose condition of the bowels is helpful. The old women have noticed this and you have no doubt often heard them say their bowels have been checked too soon. And it is correct they should not be checked too soon, but should be cleansed out with castor oil, as often as the stools show indications of fermentation and putrefaction. I give the castor oil for two reasons: 1st, because it retards bacterial activity; 2nd, because it cleans out the alimentary tract better than anything else and I might add, it is sedative and healing.

I cannot take up infant feeding here, it is too large a subject for this paper. But this you will have to master in a way and adapt to each case; you will have to shift your percentage, change your dilutant and foods until you find one the child can digest.

Return to milk as soon as you can, but *very carefully*.

Those of you who have witnessed the lightning-like change in a child that seemingly was getting well, after returning to milk, can understand this injunction.

This explosive action of the toxic bodies in alimentary tract, whether produced in cow's milk by overheating, according to Brush, or by a typo-toxiann (a poisonous alkaloid formed during the decomposition of milk), according to Vaughan, I do not know.

The medicines that have served me best are calomel, bismuth, salol, the sulphocarbonates, and some of the silver salts. I rarely use opiates in any form. 1st, because children bear them badly; 2nd, because I think they are contraindicated where toxic materials are shut up in the system. In this disease the bromides will relieve the nervous condition better than the opiates because it is a neurotic toxemia.

Brandy and digitalis are indicated.

Inherited Predisposition to Diabetes.—Heiberg quotes Frerichs' 10 per cent. of 400 cases of diabetes in which an inherited predisposition might have been inriminated; Kulz' 25 per cent. of 592 cases; Naunyn's 17 per cent. of 398; von Noorden and Williamson reporting about the same percentage, while Schmitz found a history of diabetes in other members of the family in 47 per cent. of 2,115 cases. Heiberg tabulates the data he has learned from investigating the family history among 100 diabetic and 100 other hospital patients of the same class, not including any pay-patients. Only seven relatives with diabetes were found among the 100 non-diabetics while the corresponding number among the 100 diabetics was eighteen. The diabetes had commenced before the age of 10 in seven of the 100 cases and in eighteen between 10 and 20. In 90 per cent. no cause for the diabetes was known; in the others there was cirrhosis of the liver or lithiasis. Even making due allowance for the fact that a history of diabetes in the family is more likely to be learned by a diabetic than by the non-diabetic, still the preponderance of evidence is in favor of heredity as a predisposing factor.

Systemic Gangrene.—Udaondo says that Raynaud's disease is comparatively frequent in Argentina, the humidity of the climate being possibly a contributing factor. The history of the affection is reviewed and the importance emphasized of Peletes and Bonnin's two recent cases in which Addison's and Raynaud's diseases were associated in adults, and of a case reported in 1908 in which Raynaud's disease became accompanied later by exophthalmic goiter. Voivenet and Fontaine have also reported six cases of Raynaud's disease accompanied by perverted thyroid function. In two cases in Udaondo's own practice, the symmetrical disturbances in circulation developed in previously healthy individuals. He regards Raynaud's disease as shown to be a series of symptoms resulting from some toxic action on the nerve centers or the peripheral branches. Even in the so-called idiopathic form—which is encountered in about a third of all cases—there must be some latent infectious process or disturbance in some organ with an internal secretion as the primary source for the toxic action.

Polygrams of Moving Organs.—The principle of the moving picture is applied by Levy-Dorn and M. Silberberg, only they make the two or three exposures all on the same place without changing it. The resulting composite picture shows the varying outline of the organ at the different periods, and gives instructive oversight of the motor conditions as they show by a number of examples.

THE NEXT MEETING

The next meeting of the Kentucky State Medical Association will be held in Louisville, at the First Christian Church—Dr. Powell's church—on October 29, 30 and 31.

A REPORT ON THE STATE BOARD OF HEALTH.

We esteem it a great privilege to publish the conclusions of Mr. Wickliffe Rose, the Executive Secretary of the Rockefeller Sanitary Commission, as a result of his recent trip to Kentucky. They are so important that we trust this letter will be read by every one interested in the betterment of health conditions in Kentucky.

Mr. Rose, as might have been expected in so astute an observer, has grasped the secret of our success in his reference to the wonderful organization of our medical profession. When it is understood that the activities of the State Medical Association are primarily for the betterment of health conditions and that every doctor worthy of the name in Kentucky is cooperating in this great work, nothing else but the splendid results he mentions were to be expected.

The important thing about it all is that every resident in Kentucky is under suspicion until at least two examinations have been made of specimens of his feces, and no one should rest content without having this examination made.

DISPENSING.

It seems perfectly natural that a good deal of confusion should have arisen in the past few years between physicians and druggists on this important subject. In an active, general practice in the country it is practically

impossible to write prescriptions for any considerable number of cases and the medicine must be dispensed by the general practitioner. There is no law on the Statute books to prevent this, and there should be none. On the other hand, no physician should permit himself to keep on hand or sell patented and proprietary articles, about whose contents he knows nothing. We have recently received letters from a number of physicians stating that they had received letters from one person or another warning them not to dispense or sell drugs. Of course this is all nonsense. Every physician has a right to supply such articles as may seem to him proper to his patients, and may compound his own prescriptions. It is a violation of law for a physician or, for that matter, anybody else, to sell habit-forming drugs. This is as it should be, and a doctor who would sell morphine, or similar preparations, or mixtures containing these things, to the people ought not only to be prosecuted, but is unworthy the name of our great profession.

BUBONIC PLAGUE: A POSSIBILITY.

The following excellent and timely editorial is reproduced from the August *Maryland Medical Journal*:

Word has been received that bubonic plague is prevalent in the islands close to our shores. Cases of true bubonic plague have been reported in Santiago, Cuba, and other cities near our coast. Several years ago there was an epidemic of this disease in San Francisco, Cal., which was only stamped out at great cost and energy. At that time the director in control of eradication was Dr. Rupert Blue, now Surgeon-General, United States Public Health and Marine Hospital Service. He waged an energetic and successful fight, and also warned the Eastern

cities by a statement that they might at any time expect to be visited by a like calamity unless they took measures to banish the rat. This notice has not been heeded, and with the disease so close at hand its presence amongst us may be expected at any time. Eternal vigilance is the price of success. In this case is meant the banishment of the rat. For plague is primarily a disease of rats, whence it is conveyed to man by rat fleas. The method of elimination of the disease is therefore obvious. Get rid of the rats. The destruction of rats gets rid of the fleas, and as fleas are a necessary link in the chain of conveyance of the affection from rat to man, the disease cannot be carried. Dr. Blue during his San Francisco experiences proved the possibility of the eradication of the rat. He accomplished this apparently impossible task first by starving the rodent. This was done by placing household waste and garbage—the food of the rat—in air-tight metal garbage cans with tight-fitting lids. Particular attention must be paid to this detail, and no waste or possible food must be left about the dwelling. The premises must be kept scrupulously clean. Boxes, waste, rugs, etc., which offer a harbor, must be removed, so that the animal cannot find a place of concealment. Render the rat homeless. Force him out of his burrows under old buildings and planks. Compel him to come out into the open, where he will be easy prey to dog or cat. The dog will be found especially valuable in the work of destruction. If the harboring places of the rat are destroyed, his elimination is an easy matter. Old plank walks should be taken up and replaced with concrete. Dirt-floor cellars should be concreted. Back fences, which afford a convenient run, should be taken down. The stable is a favorite home for rats. The manure affords a warm and comfortable nesting ground, and the food bin a plenteous source of food. The plank floors should be replaced with concrete, the grain kept in metal-lined bins, and manure should be stored in metal-lined or concrete pits and removed at least once in every eight days. One of the greatest drawbacks to the control of plague in San Francisco was the constant addition of infected rats from newly arriving ships. This obstacle was overcome by placing wire screens over the sewer outlets. The grocery shop, the market, the butcher shop are under present conditions infested with rats, as they offer an abundance of provender. San Francisco proved, contrary to public opinion, that rat-proofing was possible in these establishments. "A wise old rat" is a common saying, and there is no doubt but that the rat is a cunning animal and full of resources, but a starving rat is not so particular as to his food. In better times he will pass by poisoned tidbits, but

in dire distress and an empty stomach such a little thing as poison in food is apt to be overlooked. New Orleans and Norfolk are alive to the possibility of introduction of plague into their ports, and have taken time by the forelock. The health authorities of those cities are paying five cents for every rat head brought to the department. It is not amiss that the Board of Health of Maryland, and especially that of Baltimore city, start a campaign for the destruction of the rat, and thus limit the likelihood of the appearance of the plague. For without the rat there can be no plague.

HOW TO STUDY.

No professional man worthy of the name fails to study; when he deludes himself into the belief that his mental capacity is such that he does not need the elevating and enlightening experiences of others, that he feels that he can dispense with good hard and continuous study, then he is suffering either from an egocentric state, has fossilized, or is simply, in plain language "lazy, trifling, and good for nothing." "Helps to Study," is the title of a short article in the August *Popular Science Monthly*, written by Prof. Jos. W. Richards, of Lehigh University. We quote: "To study, means to concentrate the mind and attention on the subject, and to keep it there until the difficulties are mastered and the subject understood." We might parenthetically remark that it takes a certain caliber of brain to be capable of study, and that the subject studied must be within the range and capacity of the cerebrating cerebrum.

His suggestions are excellent, and as the first enemy to good study he mentions a roving attention, the allowing to come into the mind of thoughts or recollections foreign to the matter being studied. These lapses are usually the result of a weakened inhibition, for it is absolutely essential that the mind in its activities should be kept well in hand, and that the personality of the individual be the master, and compel it to do what it will. Concentration then, and the control of the direction of mental activity is oftentimes a good gauge of mental power.

Another disturbing feature is noise or interruption, and he well says that it makes no difference as to whether it is as melodious as the finest music, its action, of course is to distract the attention. Personally we agree with Prof. Richards, and it is to be regretted that students, and this should include those made hoary headed in any work that they may have followed, do not learn early in life to so control the current of their thought as to make them more or less oblivious to noise.

and sounds around them. We all recall some interesting cases of intense concentration, and the failure to hear sounds and noises about them, especially the story told of Archimedes at the time of the siege and sacking of Syracuse. This ancient mathematician (and inventor of the endless screw) was not aware of the turmoil of war, the slaughtering and destruction of men, women and children around him, but so absorbed was he, that when the soldiers broke into his room, with drawn swords, he merely exclaimed "Eureka! I have found it." My personal experience has been that if we will study a book or article, with a view to marking the essential and excellent parts, underlying them, this will have the tendency to concentrate the attention, and will afford an excellent synoptic review of the book or article.

Prof. Richards says that in day time, the light should come side ways, and at night that the student's table should be the center, or focus of the light, and the rest of the room in semi-darkness or darkness. Thus, brie-a-brac and the olio podrida of the modern room would not distract. We quote: "A lighting scheme, which lights the whole room is worse than useless, it is undesirable. The better the book is lighted and the more the rest of the room is in comparative darkness, the easier it is for the student to keep his attention fixed on the book and the less is he distracted by seeing the other things in the room. Is it not an old trick of the artist, to focus and hold the attention by the brilliantly colored "center," (such as the child's face in Corregio's "Holy Night"), in the midst of an obscure background." This is indeed true, and we congratulate the author upon his selection of such an artistic illustration. He believes in a green shade over the light, with enamel white inside, and the stand placed a little in front and to the left. He recommends the oil student's lamp, but where it is possible, the reviewer would much prefer the use of the tungsten lamp of not too great candle power, for as he well says "we see the print by contrast of nearly black against nearly white; with no illumination there is no contrast, as the illumination increases the contrast becomes better and reading is easier. At a certain point the contrast is greatest and reading easiest." If the light is right, most of us can read and study without fatiguing the eyes, and thus at one and the same time, conserve our energies and progress with our studies. I presume that it may be truly said of a great many in the profession that they do not study.

"Pity 'tis, 'tis true, and 'tis true, 'tis true."

CURRAN POPE.

ALCOHOL AND THE ANTARTIC POLAR EXPEDITION.

Speaking in general, broad terms, alcohol is not a stimulant; this statement would be combatted. I would venture the assertion, by eight out of ten men, who have not given the matter any study or real scientific observation. Alcohol should never be considered a beverage; it is a drug, a poison, and belongs to the group of chloroform, ether, et al. In the long run, alcohol devitalizes, lessens function and stimulates the growth of certain tissues that are destructive of the parenchyma of various organs. The skillful and learned physician dislikes, and often dreads the alcoholic factor in his patient. It is one thing that must be considered whenever a prognosis is given; it colors and tinges every factor in the makeup of an individual! It acts more promptly and with greater severity upon the young and women than upon men. It is probably the most notorious degrader of morals, being more frequently employed by the unscrupulous in this manner than any other measure. Its free imbibition and distribution may make a man "a good fellow," but it oftentimes ends by making him "a bad patient," and it might be added, a bad insurance risk.

Upon the central nervous system and upon mentality, its pernicious influence is always shown. The false feeling of stimulation, is oftentimes in reality, the inability to comprehend ones own mistakes and lapses. That it is the basis of some forms of delusions is unquestioned; especially the delusion of marital infidelity.

Dr. Jacques Liouville, the physician, surgeon and naturalist who accompanied the Charcot expedition to the South Pole has given an account of some experiences he had on this Antartic expedition.

While he was on the "Pourquoi-Pas," he had an opportunity to observe the effects of the absence of meat and vegetables, which produced in several of the crew a polar malady, with the symptoms of scurvy, anemia, etc. He had three surgical cases to handle. His comments are illuminatingly brilliant and may be summed up as follows: Recovery was highly satisfactory, said the Doctor, and very prompt, due possibly, he thinks, to the entire absence of pathogenic bacteria, and partly to the fact that there was *not a trace of alcoholism in the patients*. No polar expedition permits the use of alcohol in any way, shape or form; it is too dangerous a poison for men engaged in the hazardous and strenuous dashes that are made in the polar regions. The Doctor takes a just pride in the fact that this was the first polar expedition, which ever restored all its members to their homes in a perfect

state of health. To the neurologist, who sees so many of the finer misfortunes of alcohol, these statements come as an interesting verification of well known facts.

CURRAN POPE.

AN OPPORTUNITY.

Under the head of official announcements we are publishing a communication from Dr. W. H. Forsythe, who may, at present, be reached at 148 East Broadway, Louisville, where he is staying while on a furlough. Dr. Forsythe is a distinguished member of the State Medical Association, and no more interesting statement of the great opportunities open to physicians in foreign lands has been made than in this powerful appeal he writes.

It is not necessary for the JOURNAL to say that a similar opportunity is open to every physician in Kentucky. As one goes about healing the sick it is impossible to neglect the greater opportunity of teaching the great lessons of a better life here and hereafter. No profession—medical or otherwise—in the whole world is doing more along these lines than the splendid medical profession of Kentucky. Dr. Forsythe is a conspicuous example, and it is a pleasure to assure him that hundreds of his confreres here in Kentucky are serving the Lord and their fellow-man along the same lines and in the same way that he is doing. The opportunities mentioned in Dr. Forsythe's communication are great, and if any of our profession are interested it will be well for them to communicate with him while he is in the United States.

ILLUMINATING CORRESPONDENCE.

In the forum, we are publishing an illuminating correspondence between one, H. D. Edgers, who seems to be the distributor for a brand of whiskey from Louisville, and Dr. T. C. Holloway, of Lexington, which is self-explanatory. We wonder how many physicians received this outrageous letter and we would like to know if anyone of them has reached so low a stage as to have responded favorably to this insulting offer so that steps might be taken to purge the profession of such disgrace. We trust, however, that there was not a single Kentucky doctor so thoroughly lost as to have entered into this dishonest traffic.

Artificial Cell Production.—Delfino's illustrated article explains the chemical production of crystals and colloids and shows how it is possible, with inorganic salts and colloids, to produce imitation of natural cells. The artificial cells have a nucleus and undergo mitosis and can be stained, fixed and preserved by the ordinary methods of histologic technique.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

RELIABLE MEDICINES.

Articles found eligible by the Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies."

BISMUTH BETA-NAPHTHOLATE (Bismuthi Betaphtholes) is a bismuth salt of beta-naphthol. It is a brownish or greyish powder without odor, almost tasteless and insoluble in water. It is decomposed into its constituents in the intestines and hence is used in catarrhal and fermentative gastro-enteric disorders, such as gastritis, dysentery, diarrhea, etc. Dose, for children 0.1 to 0.3 gm. (1-2 to 5 grains) and for adults 1.5 to 5 gm. (22 to 75 grains) daily.

BISMUTH BETA-NAPHTHOLATE, Mulford complies with the description given above. It is also marketed in the form of tablets each containing 0.3 gm. (5 grains). H. K. Mulford Co., Philadelphia.—*Jour. A. M. A.*, June 15, 1912, p. 1857.

REFORM IN MEDICINE.

POLITICS AND QUACKERY.—The community of interest between certain politicians and quacks is evidenced in the appointment of a congressional committee to investigate the fraud order issued against the cancer cure concern conducted under the name of Drs. Mixer. The evident purpose of this committee is to whitewash C. W. Mixer of Hastings, Michigan, who conducts the cancer cure concern. As a further illustration of the community of interest C. W. Mixer is advising his prospective Chicago victims that he has been appointed assistant sergeant-at-arms to the coming Republican National Convention.—*Jour. A. M. A.*, June 15, 1912, p. 1862.

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

THE RADIUM CONTENT OF DIORADIN.—An examination of a specimen of Dioradin made in Holland indicated that but 1-1000 of the claimed amount of radium was present. While examination of one specimen is no proof that all specimens of Dioradin contain but a small fraction of the radium which they are said to contain, it proves at least that the manufacturer's claim should be viewed with suspicion. Physicians who are asked to use this preparation should refuse to do so until it has been approved by the Council on Pharmacy and Chemistry.—*Jour. Mich. State Medical Society*, June, 1912, p. 358.

TRENCH'S REMEDY.—Trench's Epilepsy Cure is sold in Great Britain in the form of a liquid containing potassium bromid and ammonium bromid. In the United States it is sold in the form of a powder which was reported to consist of potassium bromid, 61 parts and moist brown sugar, 39 parts. When this was dissolved in water, according to directions, the finished mixture was calculated to contain potassium bromid 120 grains in each fluid ounce. It is thus seen that this nostrum like all other "epilepsy cures" depends for its virtue on bromids which given in quantities larger than any physician who respects his patient's welfare—or his own reputation—would dare to prescribe, produces effects that impress the layman with their potency. Those who purchase these "epilepsy cures" mistake a temporary suppression of the attacks of epilepsy, produced by large quantities of bromids, for a cure.—*Jour. A. M. A.*, June 29, 1912, p. 2043.

TAKING THE MEASURE.—At one time the Tilden Company, New Lebanon, N. Y., stood rather well with the profession and hence it has been a surprise to some that none of its preparations are found in New and Nonofficial Remedies. The reason is given in a report of the A. M. A. Chemical Laboratory on Hydrocyanate of Iron—Tilden. The report showed that the firm held the composition of the remedy a "trade-secret"—analysis showed it to be a mixture of Prussian blue and tale—and that the statements made regarding it, if not absolutely false, were at least distinctly misleading. A recent prosecution of the Tilden Company for misbranding its acetanilid-phenacetin mixture, Febrisol, shows that the firm's policies have included deception.—*Jour. A. M. A.*, June 29, 1912, p. 2043.

TAKA-DIASTASE AND LIQUID TAKA-DIASTASE.—About three years ago the Council on Pharmacy and Chemistry rejected Taka-Diastase and Liquid Taka-Diastase because examination showed that the products on the

market did not comply with the claims made for them. Recently it was decided that a re-examination should be made to ascertain whether the preparations were now in accord with the claims made for them by the manufacturer. The examination having shown that unwarranted claims are still made the committee which made the examination recommended that the rejection of Taka-Diastase and Liquid Taka-Diastase be allowed to stand. The report having been submitted to Parke, Davis & Co., this firm reiterates its claim for the digestive power of Taka-Diastase, but admits that it will not reduce the stated amount of starch to the colorless end-point in ten minutes (the standard method for the valuation of diastase). It further states that it would change the word "digest" on the label to "liquify". In view of the contention of Parke, Davis & Co., the Council referred the entire matter to a member of the Council's staff of clinical consultants for final recommendation. This referee concludes that the claims of the manufacturers regarding the strength and properties of the material are erroneous and exaggerated; that the literature still sent out by Parke, Davis & Co., is misleading; and that if substitution of the word "liquify" for "digest" were endorsed by the Council confusion would result which would give an exaggerated and false value to Taka-Diastase. The Council accepted the recommendation of the referee and voted that the rejection of Taka-Diastase and Liquid Taka-Diastase be allowed to stand.—*Jour. A. M. A.*, July 6, 1912, p. 50.

OFFICIAL ANNOUNCEMENTS

REPORT OF THE EXECUTIVE SECRETARY OF THE ROCKEFELLER SANITARY COMMISSION ON HEALTH CONDITIONS IN KENTUCKY AFTER A VISIT AND INSPECTION.

July 20, 1912.

DEAR DOCTOR:

I have just returned from Kentucky. You may be interested in a few facts picked up on this journey afield:

1. The last Kentucky Legislature enacted a law authorizing the State Board of Health to conduct a summer school for county health officers and making it obligatory on all county health officers to attend the school, the counties paying the expenses. This school was held in Louisville July 8 to 11. In addition to the health officers many county judges were present and took an active part in the work.

2. The program covered in its main outlines the work of the county health officer; the

instruction was definite, concrete and effective; the principal themes were illustrated with lantern slides, maps and other exhibits. The meeting was immensely valuable; it marks a new day in the public health work in Kentucky.

3. Hookworm disease, because of its importance and because of its being new to the health officers in this State, was given more emphasis than any other subject. This instruction brought immediate results; when I left the laboratory at Bowling Green on the morning of the 15th there were about 1,000 specimens on hand, most of them from county health officers.

4. All the lectures on hookworm disease that I heard in Kentucky impressed me with the value of local pictures. Dr. Locke gave at Louisville the most effective series of illustrations that I have seen; he had made his own slides from photographs which he had made of mountain homes, the sanitary conditions, the people whom he had treated in his own district. The story was from his own experience; it was irresistible. A man's best working tool is his own capitalized experience.

5. Dr. Locke is trying a new method of administering the treatment. The patient takes the first dose of salts Friday night or Saturday morning; the second dose of salts Saturday night; on Sunday morning the thymol is taken in three parts at 6, 7, and 8 o'clock, the patient remaining in bed; at 10 o'clock the last dose of salts is given and the patient gets up. He reports that as far as he has been able to make a second microscopic examination, 90 per cent of his patients have been cured by one treatment.

6. Out in the field I saw the most eager and intelligent response on the part of the people to our work that I have seen any where. On Thursday, Friday, Saturday and Sunday, July 11 to 14, I went with Dr. A. T. McCormack on a tour of preliminary inspection through some of the more remote rural districts of Edmonson county. Dr. Heizer, the vital statistician, and a microscopist were with us. On Friday afternoon at Brownsville Dr. Heizer and I went up to the public school, made a group photograph of the children, gave them a talk on hookworm disease, and asked that each child give us a specimen for examination. Dr. Heizer having expressed doubt of our ability to secure specimens in this way, the request was made primarily as a test of the attitude of the children. Miss Fox, the teacher, gave support, and practically all the children brought in specimens next morning.

That evening the court house was crowded with people from the little town and the surrounding country to hear the illustrated lecture on hookworm disease. Dr. McCormack announced that persons desiring examination

could secure containers at the close of the lecture; that if they would bring in the containers on the following morning, the microscopist would examine them and that all persons found infected would be given free treatment. By 8 o'clock next morning the specimens were coming in; by 10 o'clock he was overwhelmed and had to announce that specimens would be sent to the laboratory for examination and that he would return later to conduct a free dispensary.

On Saturday at noon we arrived at Bee Spring where a lecture had been announced for 2 o'clock at the school house. We had to adjourn to church to accommodate the crowd. The church had to be darkened for the lantern; it was the hottest place I was ever in; but the people heard the last word and remained after the lecture to get the containers for specimens to be sent to the laboratory. The leaders at this meeting were the local representatives in the State Legislature and local collector of vital statistics. I was greatly impressed with the effectiveness of these local registrars of vital statistics as an agency in this campaign of education.

7. Of all my observations in Kentucky, the thing which impressed me is the effective organization, the enthusiasm, the aggressive energy of the State Department of Health, and the way in which it is enlisting other agencies in public health work. Every person connected with the department is fired with the spirit of service; every person, whatever his own specialty, is ready at all times to lend a hand in any department of the work. Dr. Heizer, for example, is vital statistician; but his chief concern is not to make statistics, but to make his statistics *vital*, to make his facts tell a story and get this story to the people. If you had seen him in action on our journey afield, you would have thought the eradication of hookworm disease in Kentucky was his special task. Dr. South has charge of the laboratory. She is not content merely to examine the specimens that are sent in to her; she has caught the idea that the laboratory was established to serve the people of Kentucky, to be an aggressive factor in bringing about better health conditions in this Commonwealth. To this end she goes to the people with illustrated lectures and demonstrations, to show the people what the laboratory can do and how they can use it for their own good. At the Louisville meeting she gave an illustrated lecture and had a laboratory running in an adjoining room for the three days. In addition to other work, she had hookworm specimens enough to keep two microscopists busy. She went before the State Federation of Women's Clubs at the recent annual meeting, gave an illustrated lecture and appealed to about 800 representa-

tives of the club women of the State as a patriotic duty to have their own families examined for hookworm infection, to get their neighbors interested and put the matter before the clubs which they represented. She followed this up by writing a letter to each of these women and sending the containers. It is not surprising that this makes work for the laboratory. It gets overwhelmed then increases its force. When other funds had been exhausted, the State Medical Society supplied funds for the salary of the microscopist to examine specimens for hookworm disease; Dr. McCormack asked his Council to take enough from his own salary to pay another microscopist and now they are wondering where the next is to come from.

Then they have enlisted Dr. Mutchler, the biologist at the Normal School. There isn't a more effective health officer in the State; each year he teaches these health lessons to about 1400 public school teachers. He was at Louisville and gave one of the best illustrated lectures of the course.

I know no state in which the medical profession is so well organized. In the survey of the State for hookworm infection the physicians have given indispensable cooperation. The State Board of Health keeps in constant touch with them and calls on them for definite service and they give it.

I repeat, the thing which most impressed me was the aggressive energy of the State Department of Health and of all persons connected with it; the way in which the work of each department is reinforced by the sympathetic and active cooperation of all; the passion of service which is becoming contagious and enlisting the citizenship of that State in making better health conditions for the people.

Very sincerely yours,

(Signed) WICKLIFFE ROSE.

THE PHYSICIAN'S OPPORTUNITY IN NON-CHRISTIAN LANDS.

In those countries like China, India, Africa, Korea, Arabia, Persia, and many others, as well as many of the Islands, are a multitude of people who have no adequate provision for their sick and suffering. In these countries, through the absence of Christianity and in consequence, great multitudes suffer and die every year, and a vast amount of it is needless and might be prevented.

Great epidemics, like the recent one of plague, in Manchuria, sweep thousands and thousands into eternity. In addition, cholera, mumps, malaria, typhoid, typhus fevers, beri-beri, many kinds of diseases due to intestinal parasites, and multitudes of other preventable diseases add their yearly harvest of precious lives.

Lack of sanitation, disposal of sewerage, and soil protection add to the unspeakable conditions in these lands. The native treatment of disease is to say the least crude; in many instances barbarous.

Surely the tender chord of sympathy in a physician's heart should be touched at this "great open sore of the world," waiting for some one to come and heal. Bright young men are waiting to be taught medical education. Great systems of sanitation and reform are to be worked out. In China alone there are opportunities beyond the human imagination, for Christian physicians who are willing to invest their lives in the greatest enterprise in the world. Hospitals and colleges are to be established; diseases stamped out; despair and death to be changed into hope and life. Think what it would mean to stamp out leprosy in these lands, which it is almost safe to say, by proper efforts could almost be stamped out in one generation. Great fields of investigation are open to research work. Surely this is a life that would appeal to any Christian physician, who is able to go.

Isabella Bird Bishop, the great world traveller, after looking upon the suffering in these lands said, "The need was so great, that unless prevented, it would induce all who could do so, to enter training as a medical missionary." David Livingstone, of Africa; Peter Parker, of China; and many others have added glory to our profession.

There are less than 1,000 medical missionaries in the needy fields of the world to-day. There is a call for a number of men, ready and willing to undertake this great work, from various places. Information regarding these places can be obtained from Mr. Wilbur Smith, 125 E. 27th St., New York City.

The different churches are calling for medical men to-day. Those wishing to go should apply under their own church Foreign Mission Board. Travelling expenses, a home, and usually a hospital are furnished. The object while it is to relieve suffering is, *primarily*, to bring the knowledge of our Lord Jesus Christ to these people.

The Southern Presbyterian Church is calling for one man for Africa; one man for Korea; several for China. For information as to these places write to Executive Committee Foreign Missions, 154 5th Ave., Nashville, Tenn.

These are only instances of the numerous calls. May many Christian men answer. "Also I heard the voice of the Lord, saying, Whom shall I send, and who will go for us? Then said I, Here am I; send me."

W. H. FORSYTHE, M. D.,
Medical Missionary.

PRELIMINARY PROGRAM

SCHEME OF WORK

LOUISVILLE MEETING, 1912				
HOURL	Tuesday	Wednesday	Thursday	HOUR
MORNING SESSION				
8	(8) HOUSE OF DELEGATES	(1) CLINICAL SURGERY	(8) HOUSE OF DELEGATES	8
9	OPENING SERVICE	(1) CLINICAL SURGERY	(1) SURGERY	9
10	(2) EYE DISEASES OF CHILDREN	(2) EAR, NOSE AND THROAT DISEASES OF CHILDREN	(2) DISEASES OF CHILDREN	10
11	(3) PHARMACOLOGY AND THERAPEUTICS	(3) PHARMACOLOGY AND THERAPEUTICS	(3) PHARMACOLOGY AND THERAPEUTICS	11
12	(4) ORATION IN MEDICINE	(1) ORATION IN SURGERY	(6) ADDRESS	12

8	ADDRESS OR SOCIAL SESSION	ADDRESS OR SOCIAL SESSION	(8) ASSOCIATION OF COUNTY OFFICERS	7

PROGRAM OF GENERAL MEETING

OPENING SESSION--TUESDAY, 9 A. M.

Call to Order PRESIDENT J. G. CARPENTER
 Opening Prayer
 Address of Welcome
 Response
 Installation of the President.
 Address of the President.
 Report of the Committee on Arrangements.

ADDRESSES

President's Address at 9:40 A. M. Tuesday.
 Oration in Medicine at 12 M. Tuesday CURRAN POPE
 Annual Address at 8 P. M. Tuesday.
 Oration in Surgery at 12 M. Wednesday ARCH BARKLEY
 Address on Preventive Medicine 12 M. Thursday.

SECTION ON SURGERY

G. A. HENDON, Chairman. A. D. WILLMOTH, Secretary.
 PROGRAM.

Our idea of arranging this feature of the program is to invite two local surgeons to serve as a Committee at each hospital and arrange with the Hospital Authorities for the admission of visitors and for the presentation of clinical material.
 We will issue tickets for each hospital in number corresponding to the capacity. The City Hospital has a large amphitheatre. No tickets will be issued or required to attend clinics at the City Hospital.

SECOND DAY--WEDNESDAY, 8 TO 10 A. M.

PLACE OF CLINIC. COMMITTEE IN CHARGE.

Children's Free Hospital A. M. Vance, J. L. Richardson
 Deaconess Hospital H. H. Grant, J. H. Penke
 Jewish Hospital Oscar Bloch, August Schachner
 Norton Memorial Infirmary Louis Frank, G. S. Hanes
 St. Anthony's Hospital W. H. Wathen, John R. Wathen
 St. Joseph's Infirmary Irvin Abell, J. M. Ray
 Sts. Mary and Elizabeth's W. O. Roberts, Simral Anderson
 Louisville City Hospital Staff of the Hospital

SECOND DAY--12 O'CLOCK

Oration in Surgery ARCH H. BARKLEY

THIRD DAY--THURSDAY, 9 O'CLOCK A. M.

Certain Surgical Conditions of the Right Upper Quadrant of the Abdomen WOODFOLK BARKOW, Lexington
 To Lead in Discussion L. S. McMURTRY, Henderson
 Gun Shot Wounds of the Intestines CURTIS GRAHAM, Henderson
 To Lead in Discussion R. C. McHARDY

SECTION ON DISEASES OF CHILDREN

V. F. BOJGENS, Chairman. W. A. JENKINS, Secretary
 PROGRAM.

FIRST DAY--TUESDAY, 10 O'CLOCK A. M.

Acute Suppurative Otitis Media; Its Recognition and Treatment by the General Practitioner C. T. WOLFE, Louisville
 To Lead in Discussion M. MOSS, Bowling Green
 Infant Mortality; Its Causes and Prevention H. E. TELBY, Louisville
 To Lead in Discussion J. R. MORRISON, Louisville
 Disease of Infant and Childhood R. J. ESTILL, Lexington
 To Lead in Discussion A. W. DAVIS, Morton's Gap

SECOND DAY--WEDNESDAY, 10 O'CLOCK A. M.

Common Diseases of the Eye in Children; Their Recognition and Treatment by the General Practitioner G. C. HALL, Louisville
 To Lead in Discussion W. M. FLOYD, Henderson
 Unexplained Pyrexias of Early Childhood W. A. JENKINS, Louisville
 To Lead in Discussion J. W. PRYOR, Lexington
 Diagnostic Errors in Diseases of Children R. H. MOSS, Henderson
 To Lead in Discussion R. B. GILBERT, Louisville

THIRD DAY--THURSDAY, 10 O'CLOCK A. M.

Therapeutics of Children B. J. O'CONNOR, Louisville
 To Lead in Discussion J. J. ROPMAN, Owensboro
 Enteric Therapeutics of Childhood P. F. BARROCK, Louisville
 To Lead in Discussion J. J. ADAMS, Munfordsville

SECTION ON PHARMACOLOGY AND THERAPEUTICS

W. W. ANDERSON, Chairman. W. E. SENOFF, Secretary.
 PROGRAM.

FIRST DAY--TUESDAY, 11 O'CLOCK A. M.

DOMESTIC MEDICINE:
 Sense and Nonsense of J. J. YOUTSEY, Newport
 To Lead in Discussion G. G. THORNTON, Lebanon
 Self Medication J. H. HOHNSTET, Fort Thomas
 To Lead in Discussion J. D. LILES, Vaneburg
 Training of the Domestic Nurse J. O. JENKINS, Newport
 To Lead in Discussion W. H. STROTHER, Owensboro

SECOND DAY, WEDNESDAY, 11 O'CLOCK A. M.

(TO BE SUPPLIED)

THIRD DAY, THURSDAY 11 O'CLOCK A. M.

Alcohol; Its Therapeutic Uses and Limitations W. E. BOJGENS
 (General Discussion).

SECTION ON PRACTICE OF MEDICINE

B. F. ZIMMERMAN, Chairman. V. E. SIMPSON, Secretary.
 PROGRAM.

FIRST DAY--TUESDAY, 12 O'CLOCK

Oration in Medicine CURRAN POPE, Louisville
 TUESDAY, 2 O'CLOCK

TUBERCULOSIS:

Radiographic Diagnosis E. T. BRUCE, Louisville
 The Blood Picture EVERETT MORRIS, Sulphur
 To Lead in Discussion CARL WEIDNER, Louisville
 Pellagra J. G. OWSLEY, Laid

SECOND DAY--WEDNESDAY, 2 O'CLOCK P. M.

Experimental Nephritis MARTIN H. FISHER, Cincinnati
 To Lead in Discussion W. H. MACCRACKEN, Louisville
 Perinephritis W. L. CASH, Princeton
 To Lead in Discussion C. L. EDWARDS, Seelye
 Vascular Tension in Chronic Illness J. D. MUTTERS, Ashland
 To Lead in Discussion W. J. SHACKLETTE, Nolin

THIRD DAY, THURSDAY 2 O'CLOCK P. M.

Typhoid Carriers ARCH DIXON, Henderson
 To Lead in Discussion J. B. MARVIN, Louisville
 Arterial Sclerosis; Early Diagnosis W. C. USSERY, Paris
 To Lead in Discussion J. H. MOORE, Danville
 Complications of Typhoid Fever A. S. DENTON, Robards
 To Lead in Discussion LOUIS P. BALZER, Hickman

SECTION ON NERVOUS AND MENTAL DISEASES

GEORGE P. SPRAUKE, Chairman. J. J. MOORE, Secretary.
 PROGRAM.

FIRST DAY--TUESDAY, 8 O'CLOCK P. M.

PELLAGRA:
 Symptoms and Diagnosis M. W. STEELE, Corbin
 Unusual Types E. H. CLARKE, Lexington
 As Related to Insanity W. E. GARDNER, Lakeland
 As a Public Health Problem O. P. NUCKOLS, Pineville
 In Eastern Kentucky (Lantern Slides) J. H. HENDREN, Cary

SECOND DAY--WEDNESDAY, 8 O'CLOCK P. M.

Anterior Polio-Myelitis J. A. AVERDICK, Covington
 To Lead in Discussion R. L. BIRD, Covington

 To Lead in Discussion CHARLES W. HIBBITT, Louisville

ORIGINAL ARTICLES**RENAL INFECTION.***

By S. H. RIDGWAY, Shepherdsville.

At the outset the writer wishes it understood, that his experience has been limited, in dealing with this class of cases, necessarily, therefore, for much of the information herein produced he is indebted to the published reports of other observers.

A repetition of important data pertaining to kidney conditions, is not only permissible, but essential in order that we may get them firmly fixed in our minds.

Notwithstanding the great advancement made in the study of these conditions in the last few years, I believe that it is in its infancy.

It is an undeniable fact that a great many diseases of the kidney are never correctly diagnosed, this is true more especially of the infections, why is this true? Because of the fact that we do not have a systematic exami-

nation made of the urine. Many of the obscure troubles we meet with, would be properly diagnosed, if such urinary examinations were made.

We should take into consideration the fact that the kidney is one of the most important excretory organs of the body, then when we approach the bedside of a patient it would be well enough to ask ourselves the question, are we dealing with a healthy or diseased kidney? If a diseased kidney, what is the offending bacilli, and what effect is it going to have on the function of this most important organ in the future, as well as the present? This will depend upon the severity of the infection, and the amount of inflammation produced.

As to the frequency, Dr. Brennemann, of Chicago, says that it occurs in 1 per cent. of all the illnesses of infancy and early childhood. Dr. Abt, of the same city, says that it occurs so frequent that it should be considered a common disease in infancy. In adults not so often, but more frequent than reports show.

ETIOLOGY.

Practically all forms of inflammation of the kidney are due to bacteria; but in a great many instances other factors must be present before infection takes place. Some of the predisposing causes are such conditions that cause a retardation of the flow of urine, viz.: calculi in the pelvis, floating kidney, enlarged prostate gland, and stricture of the urethra, other causes, trauma organic condition that will lower the resisting power of the epithelium of the organ.

The active causes are, the colon bacilli, streptococci, staphylococci, tuberculosis bacilli, most frequent in the order named. These microorganisms may enter from the bladder through the ureter. We find this mode of entrance in the aged, the old men with enlarged prostate glands, when they are compelled to use the catheter for relief from retention of urine in bladder, or there may be a descending infection take place through the blood or lymphatics; it is the opinion of most observers that this is the most frequent mode of infection. There is no doubt that the various bacilli pass through the blood and lymphatic streams to the excretory organs, and if they find a suitable soil, multiply, producing an active condition, the exact pathology of it is very difficult to differentiate, it may be nothing more than a bacteriuria, without any lesion of the urinary tract, or it may be one of the numerous inflammatory conditions of the kidney, viz.: pyelitis, pyelonephritis, pyonephrosis, two or more of which may coexist.

What train of symptoms does a disease so

varied in the intensity of its attack produce? We are confronted with a condition from a mild bacteriuria, to a severe inflammatory or suppurative process, therefore we will have a varied symptomatology. Symptoms may be classified as urinary signs, such as pain and tenderness in the loins, disturbance of urination, these may be so mild as to hardly attract attention. In the chronic cases continue an indefinite time with an occasional acute exacerbation of more or less severity, or they may be acute with a very sudden onset and be very severe. In a great many cases, pain in the bladder is the most prominent symptom, this may be a referred pain or due to the irritation produced by excess of acid caused by the growth of bacteria and pus from the kidney. In a case which I wish to refer to later on, this was the most prominent symptom.

The general symptoms of renal infection may vary from those due to autointoxication from renal insufficiency to actual septicemia according to the severity of the process. Fever varying from a low to a very high temperature, very often preceded by a chill or a slight cold spell, this may occur in the acute attack, during the chronic cases, from the acute exacerbation. These attacks of fever are frequently followed by profuse sweating. There may be symptoms referable to the stomach, nausea, attack of indigestion.

DIAGNOSIS.

Any disease that presents such a varied symptomatology and pathology must of necessity be difficult to diagnose. In making a diagnosis of renal infection, it is necessary that we should examine the kidney thoroughly. If we have a history of a chill with fever and sweats, some irritation of bladder, pains in the loins, we can be reasonably sure of an infection, after getting a train of symptoms mentioned above, our attention should be directed to a thorough analysis of the urine, that will give us accurate information. In some forms we do not get such pronounced symptoms. In the chronic forms it may run a considerable time without any of the constitutional disturbances, mentioned above, but in all cases of an obscure trouble, there should be an urinary examination made. If the general practitioner is in doubt about the exact pathological process he is dealing with, he should then give his patients the benefit of the doubt by taking them to some one who is competent to make a cystoscopic examination, and use the ureter catheter, then there is no doubt of the diagnosis.

PROGNOSIS.

The course and prognosis varies markedly in different cases, depending upon the char-

acter and virulence of the infection, the accessory etiological factors present, it is better in pyelitis than when the kidney substance is involved, in acid than alkaline infection.

We must not forget that the disease is very insidious and that while we are nursing ourselves in a false security because the symptoms are unchanged, marked disease in the kidney may be taking place, which will suddenly completely change the clinical aspect. Kuster mentions four favorable factors in the prognosis, the possibility of an early correction of the urinary stasis, youth, a strong constitution, and unilateral lesion.

TREATMENT.

Treatment is preventive and active. Recognizing the accessory etiological factors, and knowing that an active bacterial invasion will take place if these factors are left uncorrected, it then becomes our duty to adopt treatment to correct them.

Dr. Apt says that soiled napkins are the most fruitful sources of renal infection in infancy. Our instruction to the mother or nurse, should be most emphatic, about not leaving the napkins on after they become soiled. Those who consult us for stricture should be advised as to the possibility of renal infection, and impress upon them the necessity of having their condition corrected as speedily as possible. In the old man, the prostate gland being enlarged, which is the most fruitful cause of ascending infection, we should adopt a more watchful attitude, so as to avoid the catheter life that is so annoying. If a man in middle life should consult us for too frequent urination at night, and knowing the importance of this symptom, to be the forerunner of an enlarged prostate, which sooner or later will give him serious trouble, we should give him positive instruction in regard to his personal care, and the possibility of future complication if our instructions are not obeyed.

Surgical treatment should be given for the relief of such conditions as floating kidney, renal and cystic calculi.

Diet should be watched after as carefully as most any condition we have to deal with, especially the acute form. We know that if the patient is a hardy eater, that the waste product of the gastro-intestinal digestion is liable to undergo putrefaction, and some of the results of such putrefaction is eliminated by the kidneys, consequently an irritation is produced that will aggravate the condition, the diet should be such as the stomach can take care of without leaving any residue.

Medical treatment depends upon the reaction of the urine and the offending bacteria. Dr. Brown takes the stand that the growth of the bacteria is inhibited in a medium of dif-

ferent reaction from what it is accustomed to, therefore he uses the bicarbonate or citrate of soda or potash if the urine is acid, if alkaline boric or benzoic acid. According to some writers this would be a dangerous procedure, because they claim that the prognosis is better in the cases with an acid infection than in the alkaline, then if we have present those bacteria that thrive better in the alkaline urine, we may substitute a severe infection for a mild. In the acute form rest in bed, diluent drinks, liquid diet and the urinary antiseptics, of which urotropin and salol is the best, will cure a majority of cases.

In the chronic and subacute forms, the use of the treatment outlined above, with a judicious use of the vaccines properly selected for each case, will work wonders. The relief of the accessory etiological factor should also receive attention before a permanent cure can be had.

After using the above form of treatment and the case still lingers, nephrotomy may be necessary, and I believe advisable.

In this connection I wish to report the following case:

F. H., farmer, age 35. Family history: Father died with pulmonary tuberculosis, mother died with Bright's disease. Personal history: Was always healthy up to eight years ago, had an attack of appendicitis, was operated upon, found abundance of pus, after a tedious convalescence he fully recovered. About four years ago, he noticed that he was unable to do the same kind and amount of work, as he formerly able to do, on account of weakness. Following this he noticed a small amount of pain on urinating, which was more frequent than usual, the urine had a very offensive, fecal odor. Attacks of indigestion, pain in the loins, extending down to the scrotum.

Last summer he went to the city to consult a specialist, he remained in the city a week or ten days, received treatment for inflammation of the bladder, returned home with slight improvement in the bladder symptoms, no improvement in his general condition.

March 21st, of this year, I was called to see him. He had a temperature of 102 following a chill, pulse 98, tongue dry, considerable thirst, pains in loins extending down to scrotum, extreme tenderness over kidneys, more over the left than right. I gave him a thorough cleaning out, with a calomel purge, gave aspirin, quinine, and urotropin. He continued to have chills, fever and sweats. I then procured a specimen of urine, it showed the following: reaction acid, specific gravity 1025, albumin, abundant; indican, abundant; cystic cells present, renal cells, none; pus, abundant; blood, occasionally; casts, none;

bacteria, colon, abundant—streptococci and diplococci.

April the 19th I gave an injection of the combined bacterial vaccine, in six hours he had a very decided reaction.

April 20th, the chill and fever was very mild; on the 21st they were absent. Every four days I gave him an injection of the vaccine. He continued to improve, gained in flesh, weighs more than ever before. In June he began to feel the old symptoms returning, he went to the city to consult his specialist again, he was again treated for inflammation of the bladder; he returned without any improvement. I then sent another specimen of urine to the city and it showed the following: reaction acid, specific gravity 1020; albumen, a trace; cells, cystic, a few; renal, none; pus, abundant; blood, occasionally; casts, none; bacteria, abundant—colon bacilli.

I have had him on urotropin, 10 grain doses four times a day, since July 1st. He has been doing some better but not as much improvement as he should. I feel that this man is carrying a condition in his kidney that some day will give him serious trouble, if not relieved. Would it not be advisable to have a cystoscopic examination made of bladder and catheterize the ureters so as to determine the exact condition?

Case No. 2: C. P. B., a black-smith by trade, age 23, family history negative. He has always been healthy, last November he began to notice an inability to do the work required of him, he would begin to ache around the loins and in the small of the back, complained of pain on urination, lost flesh and had a general weakness of the muscular system. He was under treatment for a while, not much improvement, he spoke to me about his extreme suffering at intervals, in fact so severe as to make him almost cry out, the pain is all in his back extending around to front of abdomen, sometimes it will dart down to penis, there is no pain on urinating now, only a desire to pass urine more often. A specimen of urine was sent to the laboratory, the analysis shows the following: Reaction alkaline, albumen, nucleo, abundant, mucin present, indican present, sulphates, chlorides, and phosphates increased, cells cystic and abundant, pus abundant, casts none. Shreds of mucus, bacteria, colon bacilli, micrococci enterohalis, staphylococci. This case just fell into my hands July the 30th, therefore I have hardly had time enough to give an accurate report.

STOMACH TROUBLES AND THEIR MANAGEMENT BY THE GENERAL PRACTITIONER.*

By G. G. THORNTON, Lebanon.

It is not my purpose to discuss all stomach troubles in this paper nor to go deeply into their diagnosis and treatment, but to attempt, in a practical way, to elucidate some points in those cases that give the general practitioner so much trouble where he often gives the patient very little benefit. Text books as written by the specialists on these troubles, are generally not entirely satisfactory to us men who have to deal with many of these people who are not in a position, financially or otherwise, to have a strictly scientific diagnosis and treatment made and carried out. Most, if not all, of the book-writers deal with the subject as seen and handled by the specialist as a rule, after the patient has passed from the general practitioner's management, when said patient is willing to try, or submit to, anything the doctor says. Then he is willing to have the stomach tube used, and to have the test meal and all of the chemistry that can be brought to bear on the case, and even submit to an exploratory operation to find out the pathological conditions present in order to make a more complete diagnosis.

When these patients consult the general practitioner they usually regard their trouble as of no great importance and are not willing to submit to all of these things, some of them not being willing to try for any considerable length of time a restriction in diet. Indeed many of these cases can be well managed by one who can read symptoms and signs correctly without resorting to the finer aids in diagnosis, which the extreme case may require. Here I may recall to your minds what you have so often seen in your experience in these cases, viz.: the familiarity with which the laity use the terms, indigestion, acute indigestion, and dyspepsia, and the fact of their seeming to feel that when they have told you that they have one of these troubles, that you or any one ought to be able to understand and prescribe for the condition without any further inquiry or hesitation. If this is true, as I believe you will corroborate me, that it is, there is a reason, and I believe that it is because they have been cultivated up to it in some way and in my opinion it has been mostly by the doctors who have been careless in their use of terms.

I have found that indigestion means to the layman anything from the slightest unpleasant sensation in the neighborhood of the stom-

ach to the most intense pain of appendicitis, or, of gall-stone colic.

The troubles of which I shall speak are acute and chronic, though I shall say very little of the former as they will generally get well of themselves after a short time. Acute indigestion, which manifests itself with a paroxysmal cramping pains in the region of the stomach should, I believe, always be relieved by an emetic, because attempts to relieve it otherwise is apt to result in failure and to prolong the suffering and in most cases emesis finally results before relief is obtained. In my experience I have found nothing to do this more satisfactorily than 10 grs. pulverized ipecac in capsule to be repeated in 30 minutes if needed. If the pain is very intense and the indications are for prompt relief a hypodermic of from 1-20 to 1-10 gr. of apomorphia will do the work more promptly and more completely but the nausea is much more pronounced.

Subsequent treatment 1 c.c. pill U. S. P., every 5 or 6 hours until effect is produced and withholding diet until hungry is all that is needed in these cases.

In those cases accompanied by vomiting and purging, known as cholera morbus, which the doctor usually sees after nature has gotten rid of the offending matter and is keeping up the good work very much to the discomfort of the patient, there is nothing better than 1-4 to 1-2 grain sulphate morphia and 1-100 grain sulphate atropia given hypodermically for immediate effect and subsequent treatment need be very little, in the way of medicine. Let the stomach rest till nature calls for food by hunger and then use prudence in kind and quantity for a day or so and the patient will feel better than he has for some time.

The main cases which I had in my mind when I selected this subject are those of a chronic nature, omitting cancer, ulcer, and many others less common.

Sometimes these people will come to you with their minds filled with grave apprehensions that they have heart trouble, and will tell you that their hearts beat rapidly and hard, that they have smothering spells, and feelings which they declare they can not describe, and wind up by saying they feel queer. On inquiry you may or may not find them to be constipated. They have a full feeling as if their stomachs swelled after eating and sometimes they will tell you that they feel better while eating, or that if they will eat something it will relieve them for a while. Most of them will tell you that they have a fair or good appetite. Occasionally they will suggest that perhaps they have "catarrh" and you will, if you observe closely, find that these folks, as well as other folks,

*Read before the Middletown Hill Medical Society.

who talk about "catarrh" seem to imagine that it is some kind of a fungous growth which will last indefinitely, and which has some "spook-like" characteristics. These people are nearly always nervous, sometimes hysterical and sometimes neurasthenics and need to be handled just right to keep the impression made on the nervous system from becoming too great. These cases in times past have been laughed at and their symptoms treated with levity and told that their troubles were all imaginary, and they have gone from bad to worse and either become the prey for charlatans, or worse, have become confirmed invalids or been sent to the asylum. In some of these cases the nervous element is so pronounced that it is hard to say whether the nervousness gives rise to the stomach trouble or the stomach trouble gives rise to the nervousness. In any case it is always well to take both elements into consideration in the management of these cases as it is hard to handle either satisfactorily without giving some attention to the other.

In my opinion, simple hyperacidity is seldom accompanied by constipation, and when we have constipation with hyperacidity we nearly always have chronic gastritis, or catarrh of the stomach. In hypo-acidity we frequently have a diarrhoea and again there is a condition of the stomach in which the food, instead of digesting, undergoes a fermentation and which is accompanied by eructations of hydrogen sulphide that is always accompanied by diarrhoea and aching and a general bad feeling, and which sometimes gives rise to a suspicion of typhoid fever. This condition has in my experience given the general practitioner more trouble when he comes in contact with it than almost any other condition which is so amenable to treatment when treated correctly.

Some people have naturally weak digestive organs that have to be handled, so to speak, with care while most people who suffer from chronic stomach trouble are more or less to blame themselves for what they suffer.

In considering their management, one of the first things is the causes which produce them. The one who is over-worked and who eats too rapidly, chews and masticates his food imperfectly has improperly prepared and cooked food, who eats irregularly, who sleeps too little and worries constantly is putting a strain on the digestive organs that few are able to stand without some ill effects being observed. Sometimes the cooking is such that only the best stomach can stand it and it is impossible to give the relief sought without a change in cooks as well as diet, etc. There are probably more stomach troubles due to this source than most of us imagine. All these people need is to be instructed in the way

they ought to eat and as to what they should eat. I often say to them that the human race has not yet developed a gizzard to grind the food up after it has been swallowed whole or in large lumps. If they have had teeth they should, if possible, have them filled and kept clean, and if this cannot be done then they should have them taken out and have some made. Teeth that can not be used to chew but which only serve to incubate putrid, offensive debris to be carried into the stomach only act as a menace to the stomach and should be looked after.

The individual who presents himself, saying that his appetite is fair, but that he has an uncomfortable, heavy feeling after meals, attended with what is commonly called "heart burn" and is not constipated, can usually be relieved by giving a tablet made of sodii bicarb. 5 grs; pulv. rhubarb, grs. 2; pulv. ipecac, gr. 1-4; tincture nux vomica, 7 min.; and oil peppermint, q. s., before each meal, or this may be combined with a tablet made of charcoal and vegetable pepsin. The patient should be instructed to abstain from solids, pickles, or anything which has any acids in them.

The individual who presents himself, complaining of fear of heart disease, who has been watching his pulse, looking at his tongue, and has had his thoughts turned inward and has become so absorbed in his own troubles that he can hardly concentrate his mind on anything else, and who will tell you that sometimes he thinks he is going to be paralyzed, or perhaps lose his mind, that he feels queer, that he has a heavy sensation in his stomach and chest, that he has a feeling that if he could belch a good belch he would feel better, and that he is constipated, that he feels better while eating than at any other time, that hog meat and anything sour disagrees with him and that he has burning in his stomach, and that when he takes a drink of cold water it does not seem to reach the spot, is one that is in a good way to have a good deal of trouble in getting well and unless he strikes the right man, is apt to change doctors fast and often, and to finally become disgusted with the profession and try advertisers and fakes.

These people sometimes eructate their food and will tell you that when they belch it burns their oesophagus and there is generally a decided tenderness over the stomach on deep pressure. These cases will tell you that their stomach and bowels never seem to have any life in them and that when their bowels are moving good their stomach is better.

These cases need to be dieted and instructed what to eat and how to eat. Coffee, hog ment, and all acids should be cut off. The patient should have the sympathy of the doctor

and the doctor should have the confidence of the patient. There is a hyper-acidity, a diminished peristalsis, and excess of mucus to be overcome and besides this there is the condition of the nervous system which has been brought about by this condition which has to be reckoned with. Laborious work and worry as far as possible, must be left off. The former is much easier to manage, usually, than the latter.

There is no use to tell the patient not to worry, and not to think about the stomach and heart as they will be all right, because he could as easily forget an aching tooth as the other. His mind has to be diverted in other ways and gradually brought back to the normal. Light work, going to bed early, taking a nap during the day, pleasant company, and visiting friends together with some nerve sedative—during the day, if needed, and at bed time to make the sleep deeper and sweeter, thereby getting full benefit from nature's sweet restorer. To overcome the acidity and lack of peristalsis a tablet of rhubarb and soda, similar to the one mentioned above, to which has been added 5 min. fluid extract of cascara sagrada, often fills the indications fairly well. Should this not do all that is to be desired, a teaspoonful of maltine with cascara sagrada after meals with about 5 grs. sodii bicarbonate before meals will meet the indications in many cases admirably. There is no digestive element that will make the digestive process much better unless peristalsis is increased, therefore, whatever is given must be accompanied by some laxative. If improvement is not as prompt as it should be I am sure there is nothing that will be of more benefit than washing the stomach out thoroughly once or twice a day in connection with the other treatment. This should be done when the stomach is empty, as when there is food in the stomach it is difficult to keep the tube from becoming occluded by particles of food getting in it. Sometimes even with an empty stomach, when there is much mucus, it will give trouble with the first washing. Two or three gallons of water should be used at a time, and I usually alternate with warm and cold thereby producing more of a tonic effect on the mucous membrane. I have had patients where everything else that I had tried had failed, where there was obstinate constipation, that after beginning the washing and leaving off all other medicines, the patient improved from the start and the constipation was relieved completely. Most patients can be taught, after having their stomach washed two or three times, to wash it themselves with the help which they can get at home. Probably all of these patients would be benefited by using lavage from the beginning but most

of them will not submit to it until they have tried other measures out.

Rationale of this is that it removes the mucus which covers the walls of the stomach and any debris which may remain from the former meal and leaves the stomach clean and sweet and allows the food to come in direct contact with the mucous membrane and produce the natural stimulating effect on the flow of the gastric juices which could not be when the walls of the stomach were coated over with a considerable amount of mucus. Again this contact with the mucous membrane would cause, or stimulate peristalsis in the stomach which is so essential to normal digestion. Many cases have come under my observation where I was unable to give the desired relief without this means that yielded nicely with it.

There is another condition of the stomach to which I alluded above, that causes the patient no end of trouble and finally leads to invalidism if not managed properly, and that is what I shall call fermentative indigestion. One of the most prominent and constant symptoms of this being the eructation of hydrogen sulphide and diarrhoea. The patient has a good appetite but feels badly all the time and often complains of aching all over and there is a continual looseness of the bowels. There may be many ways of treating this condition satisfactorily to you but I tried many things singly and combined before I struck the combination and I will here give it to you. It is resor-bisnol, put out by Burrough Bros. If you don't like the proprietary, just give bismuth oxide, 8 to 12 grs. and resorcin, 2 to 4 grs., in capsules before each meal, and if you don't get results promptly and sure just be a little patient because if your patient has been sick for months or, as I have seen, for years and under good doctors, too, you should not expect too much in a very short time. In from a few days to a month your treatment will tell. Of course where the condition has run on for a good while the treatment will have to be kept up for some time.

Syphilis of the Bladder.—Michailoff's patient was a woman of 39, the wife of a physician; she complained of a dragging pain in the hips and recurring hematuria during the last five years. The hip region pains had recurred at intervals during fifteen years. The cystoscope revealed numerous papules resembling the cutaneous lesions of syphilis. The Wassermann reaction was negative, but repeated a week later it gave a positive response, and under mercury and iodid internally and boric acid irrigation of the bladder, the bladder affection took a remarkable turn for the better.

AN EPITOME OF MEDICAL ACHIEVEMENTS.*

By W. J. SHACKLETTE, Nolin.

The practice of medicine, in a crude way, began at a very remote period. At the earliest date of recorded history we find the Egyptians had achieved a process of embalming their dead, that in many respects, surpassed any method known to modern science.

In the time of Moses, the Egyptians had some idea of the benefits to be derived from dietetics and sanitation. In the book of Leviticus many rules are laid down pertaining to matters of public health.

Emerging from the mythical age of the Egyptians and Greeks, other writings have come down to us relating to the practice of medicine; most notable among these, may be mentioned six volumes attributed to Thoth and Hermes. In these we find they had acquired some knowledge of the nature and treatment of disease; surgery had received some attention and a few crude instruments were described.

The inhabitants of India, many centuries before the Christian era, seem to have accomplished some things which we scarcely do at this advanced age. They are credited with having an ointment that caused the sear of small-pox to disappear; and they cured the bites of poisonous snakes with a remedy, the composition of which is not known to modern medicine.

The ancient Greeks, through the rigid observance of certain rules of culture, acquired a degree of health, strength and physical endurance that has scarcely been equaled in modern times. Though their ideas of sanitation were based upon somewhat different principles to those of to-day, they performed some remarkable feats along that line; such as the directing of the channel of a polluted river away from a city, and in another instance, causing the swift and pure waters of one stream to flow into the sluggish waters of another washing it out and cleansing it of its impurities; and at another place a high wall was built on one side of the city to protect it from foul and offensive air blown from some polluted quarter.

During all this early history medicine was clouded in mythology and superstition; and not until the time of Hippocrates does its clear and rational history begin; and for many centuries after this, religion continued to exert a retarding influence on medical advancement.

Hippocrates was a Greek physician and lived in the third and fourth centuries before Christ; he is called the "Father of Medicine."

and traced his ancestry, on his mother's side, to Hercules, and on his father's to Aesculapius, who was termed the "God of Medicine." Hippocrates was a close observer, traveled considerably and left a great many writings. He had acquired a knowledge of medicine far in advance of his predecessors. Authors have varied in the enumeration of his writings, but those appearing to be most authentic are: prognostic, apherism, the first and second books on epidemics, those on air, waters and places, articulation, luxations and fractures and the meehlic, or treatise on instruments and reduction; these with later works of Pythagorus, Plato, Aristotle and others formed the most ancient authentic monument of medical science.

The views set forth in these writings influenced the minds of leading men of medicine for centuries to come. Hippocrates formulated the moral oath that bears his name and which has, to a great extent, formed the basis of all medical ethics to the present time.

The achievements of medicine up to the seventeenth century seem few and crude when looked at from a twentieth century view, but when we consider the great difficulties under which ancient investigators had to labor, we wonder how they accomplished so much. Investigation was discouraged and in many cases prohibited; discoveries were laughed to scorn, and the discoverers often died without due honor having been accorded them. Their sacrifice and research had brought medicine from chaos and sorcery and established it upon a scientific basis, from which modern medicine has so rapidly progressed, until now it has achieved more for the world than all other human agencies combined.

At the dawn of the seventeenth century the teachings of physiology, anatomy and other branches were very limited and often incorrect; it was left to William Harvey to discover the true and complete circulation of the blood through the body. During the remaining part of the century, investigations in anatomy and physiology, made rapid progress; therapeutics made some very important gains; the most notable being the discovery of the effects of cinchona in malaria.

The discovery of this agent brought a new era in drug therapy, and its great value to malarial infected districts can never be estimated.

During the eighteenth century many important discoveries were made in all branches of medicine. Surgery had required considerable skill but the results were very unsatisfactory. Vaccination, though known to the ancients, received prominence and practical application through Doctor Jenner. Small-pox, which up to this time had been one of the most fatal and prevalent of all diseases,

*Read before the Muhlenbach Hill Medical Society.

has, through the influence of vaccination, been shorn of its virulence and is fast becoming a disease of the past.

The first quarter of the nineteenth century saw no great change or discoveries in medicine beyond a steady advance; but about the middle of this century came the announcement of the germ theory of disease; and in connection with this we might mention the names of Pasteur, Virchow, Klebs and Koch as pioneers in this important discovery.

Acting upon this theory, other important discoveries were made and the views were changed as to the origin and cause of many diseases. The mosquito was found to be the carrier of malaria and yellow fever; the flea from the rat and ground squirrel, the disseminator of the bubonic plague germ; the house-fly, unfiltered water and unsterilized milk were found to be bearers of typhoid, dysentery and other diseases.

Many other agents conveying disease germs have been discovered, and acting upon this knowledge, in destroying the germ, and in other ways preventing the infection from reaching the body, preventive medicine has come to be one of the greatest boons of science to humanity.

Close on the advent of the germ infection theory came the cell theory of growth and repair, upon which cell building therapy has been based. In this Golden Age of discovery, was added the happy discovery of chloroform and ether anesthesia, the priceless balm of surgery. Later came the discovery of other anesthetics, both local and general. Operations that hitherto were too severe to be even considered, could now be performed free from pain and shock.

Emanating from the germ theory of septic infection, followed the discovery of antiseptics. With the advent of antiseptics and anesthesia a glorious and triumphant era had dawned upon the field of surgery. Infections following the surgeon's blade and septic and gangrenous wounds rapidly disappeared; till now, septic infection following an operation, has come to be looked upon as a reflection on the precaution of the surgeon and the care of the nurse.

We can understand better what a great revolution antiseptic surgery has brought, when we go back a little longer than a quarter of a century ago and see the conditions that existed in the wards of hospitals; every wound both minor and major, were bathed in germ laden pus; blood poison, gangrene, erysipelas and that most dreaded complication, lock jaw, were common sights. In compound fracture two out of every three succumbed to the ever present infection.

With the growing confidence in antiseptic and disinfectant measures, came increased

skill in surgery. Parts and organs of the body that had hitherto been considered 'forbidden ground' to surgery are now explored with marvelous results. Persons through disease or injury, losing the function of their air passage, are now caused to breathe the breath of life through a silver tube; organs in one body are replaced with those from another, and even the heart, that sacred seat of life, whose action it was thought would cease at the mere prick of a pin, is now approached with the surgeon's knife without fear or disaster.

The once frightful death from hemorrhage is now rarely known in surgery; in fact, as sepsis after operations reflects on the surgeon's cleanliness, so a death under ordinary circumstances, may reflect on his professional skill.

The great change wrought in army conditions in the last few years, through disinfecting measures and antiseptic surgery has been a glorious achievement. The saving of life and suffering through these measures, viewed from a quarter of a century back, would approach the miraculous, and greater results will yet be achieved.

During the Civil war between the North and the South, scores of our braves fell victims to disease and septic wounds to one in battle; in the Spanish-American war, fourteen succumbed to disease to one on the battlefield; in the Boer war the battle casualties of the English, were as one to ten lost from disease, and in the late Russo-Japanese conflict, where a larger and better surgical corps was provided, the loss on the firing line was four, to one who died from disease.

No less marvelous, than the achievements of antiseptic surgery, have been the accomplishments of public sanitation based on previously mentioned discoveries. With a knowledge of the origin, and in many instances, of the conveyers of disease, preventive measures have been adopted that have borne results of worth untold, and such as would have astonished, even the gods, of the ancient Greeks.

Infectious diseases and the consequent suffering, throughout the cities of the world, have been reduced one-fourth, some one-half and in other instances almost exterminated; the death rate thereby being lowered to nearly the same extent. In the country districts, especially throughout the tropical regions, the results accomplished have been no less amazing.

Conditions in many regions that were formerly reeking with infection of malaria, typhoid, typhus, dysentery, yellow fever or visited by the bubonic plague, claiming as their victims nearly every immigrant, who would dare to approach their bounds, and at times almost depopulating large sections of country,

have been revolutionized by modern medical science. Their waters have been made to sparkle pure and clear and their wilderness places to "blossom as the rose."

Most everyone conversant with recent history knows, at least in part, what a wonderful work was wrought in Cuba and its principal towns under the direction of Doctor Wood, Doctor Reed and others; and what was accomplished here was, perhaps, more than duplicated by Doctor Cruz in Bahai, Rio de Janeiro and Santos.

In applying the same measures to the Canal Zone results have been accomplished beyond the dream of the most sanguine; the construction has been made practicable for the most gigantic enterprise ever accomplished by a civilized nation.

After the Government had spent millions of dollars preparatory to this great work of construction, health conditions proved so disastrous that abandonment was seriously considered. At this crucial moment modern scientific medicine under the direction of Doctor Gorgas, that brilliant captain of sanitation, intervened and saved defeat. When this "Eighth Wonder of the World" is completed it will be an unexcelled and everlasting monument to medical achievement.

Through the achievements of medicine this boasted "Land of the Free" has gained its greatest freedom. Diseases that man was once a slave to, and claimed their victims by the thousands, now are under his control. Pasteur, that modern genius of medical discovery, has said, "It is possible to eradicate every infectious and contagious disease from our land." The possibility of this assertion is being yearly confirmed in mortality statistics.

While the preceding enumeration of the achievements of modern medicine may, to the uninformed, seem a "Utopian" tale, yet the future for serum therapy, in its sphere, is no less promising. The antitoxine treatment of diphtheria has already been proven to be a specific of great value. If immunizing serum could be promptly administered to every case exposed to this contagion, the development of no less than ninety per cent. could be prevented; and when the serum can be administered in sufficient dose, nearly every case is promptly relieved. We can obtain some idea of what has been accomplished in the treatment of this disease by comparing the mortality under the old methods of treatment, which was sixty per cent. and often more, to the mortality of to-day, which is less than fifteen.

Serum therapy has been used with more or less good results in typhoid, pneumonia, septicemia, tetanus, tuberculosis, erysipelas, rabies, rheumatism and meningitis. Experimentations on the serum treatment of these

and other diseases, are being studiously and progressively pursued, and it is reasonably hoped that in a short time the results will be as successful in these maladies as in diphtheria.

Other agents have been utilized and made to serve useful purposes in the realm of medicine; electricity has been made to perform some remarkable feats and has come to be a valuable aid to medical diagnosis; light, air, water and heat have been found to possess elements wonderful in their economy and invaluable in their aid to modern medicine. In fact, so liberal and so broad, has nature been in her distributions, that the scope of scientific medicine facilities extend from the sunlit skies to the earth's dark interior.

Medicine, though sometimes said to not be an exact science, has achieved more for man than any other science; it conserves life and health, man's most valued possessions. Let us note some of the recent effects along this line; in the last century London has lowered her death rate, per year, from forty per one thousand inhabitants, to fifteen at the present time; Berlin from thirty-three in 1875, to sixteen in 1904; Munich, from forty-one in 1871, to eighteen in 1906. Havana, from one hundred and three a century ago, to twenty at the present time, and New York, from twenty-five in 1890, to sixteen in 1910. As the result of the achievements herein enumerated, the average life of the inhabitants of different countries has been lengthened from ten to twenty-five years, the greatest being that of Prussia, where scientific medicine is most progressive.

It is estimated that the average value of each person saved from a premature death is \$1,700; then, if through the influence of medicine, the death rate, per one thousand, in the United States, has been reduced from twenty-five to sixteen, or a saving of thirty-six per cent., five hundred and five thousand people annually saved from death would represent a value of \$909,000,000.

The saving in the conservation of health is also a big item; the estimated cost of illness, and loss of wages in the United States amounts annually to \$960,000,000; if medical measures have prevented, even twenty per cent of illness, it would represent a saving of nearly \$200,000,000.

We have estimated the monetary value of the prolongation of life and the conservation of health, but who can estimate or scarcely imagine, what it means for the thousands who are annually saved from disease and death and the consequent pain and sorrow.

Scientific medicine has gained the confidence of the learned, the rich and the poor. Its healing balm is equally bestowed in the mansions of the great and in the hut of the

lowly. When man is being born from his mother's womb, to first breathe the breath of life, as a helpless babe, there you will find the comforting and helpful influence of medicine to soothe the mother's pain, the sting of Eve's transgression, and to help the offspring to a safe delivery into its new realm. Countless of thousands of mothers and their cherished babes have been saved to the world and their loved ones through the skill and care of their faithful accoucheur. Had it not been for the skill of the surgeon the pages of history would have never been adorned with the mighty exploits of a Julius Caesar.

Through the care of modern medicine, thousands of children have been permitted to walk in the light and fill a useful sphere, where, hitherto, they would have groped their way in darkness and have lived a misery to themselves and a burden to their friends. Go to the remotest bounds of the earth, wherever civilized man and commerce are found and there you will find the influence of modern medicine has paved the way for his habitation and guards his most sacred interests.

In the land of the heathen, where the missionary has fallen victim to the appetite of the cannibal, the influence of medicine is leading the way and opening up the field to the spread of the Gospel to "all the world."

Lastly, when man in old age or through the disobedience of the laws of health, is brought low and tosses upon his dying couch, again the ever ready hand of the God-missioned disciple of medicine is there, to soothe his agonizing pains and to reconcile him to life's inevitable change.

History of Medicine—Park.

Inoculation of Tubercle Bacilli in Sacs.—Heymans has obtained encouraging results in his experimental inoculation of rabbits with killed tubercle bacilli in sacs introduced into the peritoneum. The sacs are made from a membrane obtained from reeds, and hold 1 gm. of the bacilli bodies. Substances dialyze through the sac and set up an action which immunized the animals in his experiments. He thinks this method of preventive and curative immunization is superior in many ways to all other techniques to date. It may prove useful in vaccination against typhoid as it permits the introduction in the most harmless way of large amounts of killed bacilli. The reed sacs are less porous than collodion sacs, and are preferable for several other reasons.

LOBAR PNEUMONIA.*

By J. W. ACTON, Glasgow.

An acute infectious inflammatory disease of the lungs characterized by chills and fever and a fibrinous exudate, and generally terminating by crisis in five to nine days.

ETIOLOGY.

Predisposing causes, exposure to cold and dampness, alcoholism, over-crowding in poorly ventilated rooms and anything that lowers the vitality.

Direct cause, the diplococcus of Frankel.

MORBID ANATOMY.

The lung presents three stages in croupous pneumonia, congestion or engorgement, red hepatization and gray hepatization. The right lung is more often affected than the left. In the first stage, or stage of congestion, we frequently have restricted movement of the affected side, and increased movement of the sound side. This part of the lung is redder and heavier than normal.

The second stage is the stage of red hepatization or solidification, and generally lasts four or five days and furnishes unmistakable signs. In this stage the lung tissue is solid and firm and airless. The third stage, or stage of gray hepatization or resolution, lasts from three to ten days, in this stage the lung is a grayish white color, is softer and more moist than in the second stage. There is nearly always some involvement of the pleura over the affected side or part of the lung.

The incubation period is generally very short. Perhaps we have no other disease so invariably ushered in by a chill as in croupous pneumonia. The chill may be the first symptom, or we may have slight catarrhal symptoms for a day or two with headache. Following the chill the fever rises almost immediately to from 103 to 105 degrees F. There is generally a distinct flush on the cheek, frequently more on the affected side.

The pulse is full and strong, heating from 100 to 130 per minute, and resisting pressure. There is generally pain in the side, if the pleura is involved the pain is sharp. There is great thirst. The urine is scant and high colored and may contain albumin. The respirations are increased in frequency and with this we have a dry, hard cough which is frequently restrained on account of the pain it causes. The patient lies on the affected side. The skin is hot and dry and on percussion there may be but a slight impairment of resonance, on early auscultation the vesicular murmur may be very feeble, but very soon we hear the distinct crepitant rale at the end of inspiration.

There is exaggerated vesicular breathing

*Read before the Barren County Medical Society.

over the normal lung. All these physical signs may not be detected, especially if we have a deep-seated or central pneumonia. In the second stage all the signs obtained on inspection in the first stage are intensified, the breathing is markedly abnormal, hurried and often accompanied with an expiratory grunt. The alae nasi dilate with each inspiration. The skin continues hot and dry and the pulse frequent. Movement is much less on the affected side and may look larger, if the lower lobe is involved the apex of the affected side may show greater movement. Percussion will give absolute flatness over solidified area.

Auscultation gives high pitched bronchial breathing over solidified lung. Usually have herpes on lips or nose. Eyes bright anxious expression, frequent short cough which causes considerable pain. Expectoration is blood-tinged and very tough. The heart sounds are heard very distinctly over the consolidated lung, while lingering crepitant rales may be heard.

In the third stage to inspection, palpation and auscultation, the phenomena of the first stage is largely repeated. The sudden drop of the fever known as the crisis is one of the most characteristic features of the disease, followed, many times, by dreaching perspiration, this is followed by refreshing sleep. Resonance is generally impaired for some time, the breathing gradually returns to normal. The skin is not so hot, the crepitant rale returns known as the "crepitans redux" and is finally replaced by normal vesicular breathing, by which time the dullness has disappeared. The convalescence is generally rapid.

Lobar pneumonia may terminate in abscess, gangrene or phthisis pulmonalis. In this case the symptoms of the second stage continue, the fever does not fall, and in case of abscess have expectoration of pus and gangrene a very disagreeable odor.

There may be modifications of the foregoing symptoms. The chill may be absent in which case the symptoms arise more gradually.

The temperature in old persons and drunkards may not be so high while in children it may be higher, the same is true of the respirations. The pain, cough and expectoration may be absent in old people, the pulse may be feeble and rapid instead of full and strong. The physical signs are sometimes delayed from one to three days in old people. According to some authors we may have an afebrile pneumonia, although I have never seen one.

DIAGNOSIS.

The diagnosis of a typical case of pneu-

monia is generally easy. The chill, high fever, hacking cough with the physical signs, are easily recognized as a rule. It is the atypical cases that give us trouble many times. Lobar pneumonia may be confounded with phthisis pulmonalis, pulmonary congestion, plenrisy, meningitis, etc. Pleurisy is the disease we most frequently have to distinguish from pneumonia. The crepitant rale of pneumonia and the friction sound of pleurisy often resemble very closely. Very valuable in diagnosis is the vocal tactile fremitus which is increased in pneumonia and diminished in pleurisy.

The exploring needle may be of great service. Blood cultures are the most positive means of diagnosis, the absence of leukocytosis speaks strongly against pneumonia.

PROGNOSIS.

Always be guarded in your prognosis of pneumonia. It is a very treacherous disease. It is about as fatal as any of the acute infectious of adults in temperate climates, always worse in crowded places. Very fatal to drunkards and those of intemperate habits. The more lung involved the more serious the attack. Death is usually caused by heart failure caused by over-distention of the right heart or it may be caused by the direct effect of the toxin on the heart and nervous system. The mortality should not exceed 15 to 20 per cent.

TREATMENT.

I know of no specific for pneumonia. Each case is a law unto itself. It is the individual not the disease that needs treatment. If possible, select a large sunny room where perfect quietness can be maintained. Have an abundance of fresh air regardless of the kind of weather, of course avoid draughts. Fresh air stimulates the heart and respirations, quiets restlessness and promotes sleep. Keep the room at an even temperature and not above 65 degrees F. Have as much light as is comfortable to the patient. Visitors and unnecessary attendants should be excluded. The diet should be easily digested, and nutritious.

I give milk, raw eggs, beef juice, ice cream, the juice of lemon, orange or grape, be sure to give patient plenty of water also give cracked ice. In the first stage and early part of second in full-blooded persons with full bounding pulse, cough, great dyspnoea and sharp pleuritic pain and later when there is engorgement of the right heart, bleeding relieves these symptoms and is thought to hasten the crisis. With those who are not so robust use acetonite. I nearly always give calomel at the beginning and follow with salines when needed. For the high fever I prefer sponging as often as is necessary to con-

trol the fever. If fever is not so high patient should be sponged as least once a day with tepid water. Keep mouth and gums clean.

For the severe pain, I know of nothing better than morphine hypodermatically. Dover's powder in 3 to 5 grain doses frequently acts well. May give liq. ammonia acetate. As an expectorant I prefer the carbonate of ammonia in 5 to 10 gr. doses, frequently repeated. I have never thought I got any benefit from digitalis. I have tried ponltices and antiphlogistine but don't think much of them. I frequently employ counter-irritation by means of a mustard plaster, also the use of an ice bag or ice-cold application to the affected side is very highly recommended by some, and I have used it in a few cases and was very favorably impressed with it.

As a stimulant at the crisis, I prefer strychnine and digitaline. For the profuse sweating I know of nothing better than atropine. Complications will have to be met as they arise. The important thing is to watch the heart and circulation and see that your patient gets plenty of fresh air and nourishment. I notice some quite flattering claims from creasotal. It is claimed by some to be as near a specific as we have. I have had no experience with creasotal, the serum treatment and quinine and urea hydrochloride.

FORCEFUL ADDRESS OF WELCOME TO THE ANNUAL SCHOOL OF COUNTY AND CITY HEALTH OFFICERS.*

By HON. MUR WEISSINGER, Louisville,
JUDGE OF THE JEFFERSON COUNTY COURT.

I want to thank and congratulate the Executive Committee of the State Board of Health in their selection of this City for the meeting which has begun to-day. It is fitting that the County which has been the most progressive in matters relating to hygiene should be selected for this great honor, and that in the metropolis of this State, this initial movement, which has for its purpose the benefit of the citizenship of Kentucky by educational methods, should be inaugurated. There is not a person present in this assembly who will not go down in history as one of those who contributed to one of the greatest movements that has ever been started in this good old State. I have included in that statement as you observe, not only every county health officer, but every person present, for I say to you that whatever the purpose of the public official, whatever energy he may put into his labors, though he toil from the rising

to the setting sun, though he bring to his work that enthusiasm which only a man wrapped up in it can, nevertheless, he needs the encouragement and the endorsement of the representative citizenship of his community. The commendation of his fellow man will buoy up his spirits when they begin to droop. I say to you, the public, that you must oversee the work of these officials, that you must not criticise their endeavors unless you have investigated the facts and that you must only come to a conclusion after you have given the matter serious and honest consideration. The acts of public officials should be observed with a critic's eye, but an unfair judgment of him by his constituents will do much to destroy the enthusiast and will produce a mere automaton. On several occasions I have publicly insisted that the one thing most necessary for success is the cooperation of all the charitable organizations and of the people of the community with the public officials. If these gentlemen here who represent the various counties of this State, and I believe that nearly every county of the 120 is represented, will be backed up in their endeavors by their constituents, then the good that will be accomplished by them will astonish you. Let not carking critics, who take no interest in humanity except to criticise adversely those who are trying to correct the evils which have so long existed, and who fail to see the good that these officials accomplish, and who seize upon the few mistakes which the official may make and point to them as proof of his incapacity, mould public sentiment. These critics constitute that portion of the community which is willing to let things be to-day the same as yesterday; who have no desire for improvement but are willing, because their father, grandfather and great-grandfather did a certain thing in a certain way, to do likewise. These are what to-day are called reactionaries, but this is not a reactionary period, this is the age of progress and the man who hopes to hold his office to-day, must be a man with progressive ideas.

So to-day this meeting means progress. We are here to-day not to consider so much what has been done but to consider what should be done. It is a lamentable fact that matters of hygiene have not received the attention from the public at large that they have deserved. There have been few men in Kentucky who have made a study of this subject and who have sought to inculcate their ideas in the mind of the public and while the seeds which they have sown have been remarkably fruitful, nevertheless, Kentucky to-day has not taken that place to which its citizenship entitles it. The Ohio river which separates the North from the South also marks the difference between States progressive in hygiene

* Delivered before the first annual meeting of the School of County and City Health Officers, Louisville, July 8, 9 and 10, 1912.

and states which have been heretofore backward in this respect. Across this beautiful river we have three of the most progressive states in the Union. I know more about the State of Indiana than I do of the other two. To-day in Indiana we find this great movement has been rapidly pushed forward. I was particularly impressed with this fact by reading a statement of Dr. Wiley published in the Sunday paper. The Doctor has come out for Wilson and Marshall and gives as his principal reason for his desertion of his life long party, that Governor Marshall of Indiana has stood for these things which will bring about pure food laws and their proper enforcement. He cites a case where the National Government by the use of its great power sought to vitiate the provisions of the State Board of Health of Indiana. Fortunately, however, that attempt failed. Now do not think that I am trying to inject into this meeting any politics, but there is not a man within the sound of my voice who has ever made a study of this subject, who does not know that Dr. Wiley has done more for the enforcement of the pure food laws than any other official who was ever in public office.

If you will pardon me I will point to a few things which Jefferson county has accomplished and mainly through the cooperation of its citizens with its public officials.

Several years ago the Jefferson County Health Officers decided to apply the tuberculin test. Like all things new, there was considerable opposition, but by firmness and that famous tact for which our friend Dr. Smock here is noted, the test was applied, and 25,000 dairy cattle were tested. These cattle for the most part supply the local markets and upon their product the sick, the infirm and the babies depend for their sustenance. This great feat was accomplished with the hearty cooperation of the authorities of the City of Louisville and to-day I point with pride to the fact that there is no city in the world which has purer milk than the metropolis of this State.

Jefferson is keeping abreast of the times and its citizens are beginning to recognize that there is no greater duty which the county owes to its citizens than to take care of their health. A human life is an asset to the community. All measures possible should be taken for its preservation. Applying the acid test of commercialism and treating the matter purely from an economic standpoint, it can be easily demonstrated that time and money expended for this purpose are productive of results which enhance the commercial prosperity of a community. "Cast thy bread upon the waters and thou shalt find it after many days."

In Jefferson county we are fighting the

white man's plague with marked success. Through the aid of the county and other sources a modern hospital for those affected with tuberculosis has been established. It is located nine miles from the City on the top of Waverly Hill. There is nothing about it which repels the patient but there is an air of welcome which immediately makes him feel at home. Aided by the beautiful scenery, pure air and the warmth of the smiles of the attendants the patient soon begins to improve. The inmates of this institution are receiving the tender care of trained officials and so successful has been the treatment that this place is rapidly being known as a mecca for those who are so unfortunate as to be stricken by man's greatest enemy. On the eventful occasion when this institution was dedicated I had the honor to address a splendid audience gathered upon its beautiful grounds. Man likes to prophesy, and among other speakers, I drew certain pictures of the future success of the institution and it is my happiness to tell you that those pictures were only incorrect in so far as they underestimated the good which that noble institution was to accomplish.

For many years this community struggled with a filter plant until it began to be a by-word. If any one desired to express doubt concerning the time when a certain thing would be accomplished, he would remark that it would be finished upon the completion of the filter plant. But to the surprise and no doubt disappointment of carping critics, one morning, water rushed through the faucets clear and pure as any from a limpid stream, and ever since, our people who for years had swallowed the mud of the Ohio river, had even grown to like it and had long since eaten their proverbial peck of dirt, have been imbibing water than which there is none purer and which is furnished at a reasonable rate.

When Louisville was first founded its southern part was full of swamps and ponds. Strangers who visited it wrote concerning it that it was finely located for business, but that it was very unhealthful. The death rate was very high. Since that period rapid progress has been made. Where then were ponds and marshes, now stand stately dwellings, until to-day the old Dutch Ditch is almost a thing of the past. Recognizing the unhealthful condition of portions of the county, the Fiscal Court has undertaken to drain that part of it where swamps now exist. Already it has expended more than \$143,000 for drainage and this year a levy has been made which it is estimated will produce \$47,000, making a total of \$190,000 which will have been expended for drainage purposes at the end of the fiscal year.

You gentlemen are engaged in a noble

work. You are members of a profession, which is possibly the noblest of all, because you are thrown in contact with those who need most the help of others. So many have adorned this profession that it would be impossible in a short time to give their names, but in passing I may mention those of Ephriam McDowell, David W. Yandell and the late lamented Dr. Wm. Bailey, the latter of whom spent the greater part of his life in the special field of preventive medicine in which you gentlemen are especially interested. I am one of those who do not believe in waiting until a man has died before something pleasant is said concerning him and even at the risk of making the gentleman blush whose name I will mention, I will say that there is no man in the State of Kentucky who has done more to promote healthful conditions than our able and distinguished Secretary. To a large extent he has been a pioneer, at times fighting against odds, always with a fixed purpose, sometimes defeated but usually victorious, a man of national prominence, a sworn foe to bacteria is Dr. J. N. McCormack. It is a tribute to his sagacity and to his devotion to suffering humanity that this splendid audience is here to-night.

Louisville has grown to be a great convention city. For years we have extended such cordial hospitality to our visitors that most of them have desired to return. Most of you gentlemen are well acquainted in this city and it is unnecessary for any one to extend you a hand, but if there is a single person who is visiting us who thinks that he needs an invitation to make himself at home, to him I extend my hand and the hands of every other citizen of this community, and say that we bid you welcome, thrice welcome. I will see that the doors of the court house are kept open and that the doors of the jail remain closed.

Believing that your stay in this city will be productive of much good as well as of pleasure, and prophesying that the profit of these meetings as well as the pleasure of attending them will increase from year to year, and hoping that the days will be so happily passed that you will almost account them as riotous merriment, and that when you leave you will say *au revoir* but not good bye, "On with the chance let joy be unconfined."

Embedding of Ovum on Stump of Tube.—Benzel reports a case of this kind, the third on record. They teach the necessity for wedge excision in removing the tube on account of a tubal pregnancy. This alone guarantees against such happenings.

COMPETENT, ALL-TIME, WELL-PAID, LOCAL HEALTH OFFICERS AS AN INVESTMENT.*

By J. N. McCORMACK, Bowling Green.

In 1911, for the first time in the history of Kentucky, under the new Vital Statistics Law, the location, cause and other essential facts in regard to deaths, 30,583 in number, were officially reported, tabulated and permanently recorded. Taking the number of deaths reported from each of eight of the leading common, every-day, domestic pestilences, known to be practically preventable, corrected by voluntary reports from physicians in response to inquiries as to what had occurred in their practice in selected years, careful estimates have been made as to the number of cases of each of these diseases during this year.

USELESS WASTE OF HEALTH AND LIFE FOR AN AVERAGE YEAR.

These returns and estimates indicate that for this particular year, which proved to be an average one, there were 31,086 cases of tuberculosis under treatment, with 5,181 deaths; 15,525 cases and 1,035 deaths from typhoid fever; 5,450 cases and 545 deaths from diphtheria; 22,480 cases and 1,124 deaths from the diarrhoeal diseases of infancy and childhood; 19,624 cases and 840 deaths from dysentery and diarrhoeas in adults; 2,160 cases and 72 deaths from scarlet fever; 31,000 cases of gonorrhoea and 16,250 cases of syphilis. This gives a total of 143,575 cases and 8,797 deaths in one year, which is believed to be fairly typical of what is occurring every year, from these eight preventable forms of sickness. Diseases ought to be important to a family, state or nation exactly in proportion as they cause sickness and deaths and cost money, but this is recognized by few of our people. One case of cholera, yellow fever, bubonic plague, leprosy or other foreign pestilence would cause a panic in any town or county. A small fraction of these 8,797 deaths in a mine or railroad disaster would send a thrill of horror through the nation, as occurred recently when the Titanic went down, but this daily tragedy of sickness and deaths from easily preventable diseases, so common that they are not feared, goes on before the eyes of every community in Kentucky almost without comment.

THE COST OF SICKNESS IN KENTUCKY.

As an economic problem, a phase of sickness seldom thought of by most people, the practical importance of the above facts to our fiscal authorities and people can hardly be overestimated. The estimate of our reporters of an average of \$94 for the medical care, drugs, nursing and loss of time for each case of sick-

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

ness, certainly a very conservative one, places the total yearly tax upon the people of Kentucky for these eight diseases at \$13,496,050, nearly double the total annual revenue of the State. But the actual loss is far beyond this. It has become the fashion to talk about conservation, limiting the term to farms, forests, water-powers, mines, factories and similar resources having recognized money value. As a matter of fact, men, women and children—people—are the greatest resource we have to conserve, and without people in such health and vigor that they can develop, operate and enjoy the farms, and other things called wealth, they have little more than an abstract value. Prof. Fisher, of Yale, the world's greatest authority upon the subject, tells us that the value of a human life gradually rises from \$90 in the first year, to \$4,200 when in full vigor, remains nearly stationary for a long time and then gradually declines until it becomes negative. He places the average value of lives sacrificed by preventable diseases in this country at \$1,700. Making this the basis of the calculation and applying it to the 8,797 deaths from eight of these diseases last year, gives the sum of \$14,954,900. Adding this to the \$13,496,050 which it costs in various ways to care for those sick of them gives a total loss for the year of \$28,450,950. Enormous as these figures may seem at first sight it is believed that they under-estimate the money saving which is entirely possible every year if all the people of Kentucky could and would observe the laws of health, as now known to the scientific world, in their daily lives. This cost of sickness is just as much a tax upon the people as if paid into the county, municipal and state treasuries, but no benefits are returned from it as is the case more or less with other taxes. It was this economic feature of sickness mainly, the useless and senseless drain upon the material resources and vitality of their respective nations, which induced Gladstone, Disraeli, Bismarck and others of like prominence in public affairs abroad to recognize, and crystallize into laws and governmental policies the truth, that "the care of the public health is the first and highest duty of the statesmen." It will be noted that preventable sickness is discussed here purely as a business matter, no consideration being given to the inconvenience, suffering and sorrow it brings into the homes of the people.

FACTS ABOUT THIS CLASS OF SICKNESS WHICH ALL SHOULD KNOW.

None of these diseases ever occur or spread except from the germ of seed from a previous case. The exact method of spread varies with each disease, but competent physicians understand the conditions and laws under which

they multiply and spread fully as well as the best farmers know how weeds spread. They know, for instance, that if all the expectorated matter and other infectious discharges from every case of tuberculosis now in Kentucky could be disinfected or destroyed and all of them either recover or die, or if all the discharges from the bowels and kidneys from every case of typhoid fever could be thoroughly disinfected before the vessels are emptied, our people would soon be freed from both of these diseases. If the people could be properly instructed, the expense of preventing these diseases would be small compared with what it now costs to have them. The history of twelve years of smallpox in Kentucky, from 1898 to 1910, is another striking example. To say nothing of the distress, suffering and loss of life, it is estimated that this disease cost our people over a million dollars. This seems strange when it is now well known to the scientific world that vaccination is an absolute preventive of smallpox, and that when properly done it is devoid of danger. Vaccination has long been compulsory in Germany and all comply with the law, with the result that for the last reported year there was but one imported case in their 64,000,000 population. The average cost of a successful vaccination for the public is 40 cents, the average expense of caring for a case of smallpox for the public is \$40, and yet in the face of this experience, over 40 per cent. of our people remain unvaccinated, enough in almost every community to spread the disease if a case is brought into it.

WIDESPREAD AND UNREASONING PREJUDICE AGAINST DOCTORS.

Most people are attached to their family physician, but few of them think or speak kindly of other members of the profession. It is but fair to say that this is largely a reflection of the way a majority of the physicians of the old school of the same community spoke of or treated each other. The profession came to recognize the enormity of this evil and the disaster it had brought upon the people, and, in recent years, it has become one of the most harmonious of the vocations. The effect of this change has only reached the more intelligent classes, and while the individual doctor stands high with a few people—his patrons—the profession as a whole remains very low in public esteem. As a matter of fact, ours is the only vocation organized as working systematically against its own interests. In so far as it succeeds in preventing tuberculosis, typhoid fever and similar diseases it diminishes the incomes of its members. This is not idle speculation. The decrease prevalence of these diseases is telling up the yearly income of almost every

practitioner in this country, and yet they persist in educating their patrons and the public in the best methods of prevention. This is because ours is essentially a humanitarian calling, in constant touch with sickness, suffering and death, and that it has been found far easier and safer to prevent than to try to cure these diseases. For much the same reason physicians do more charity every day in every year than all other vocations combined, and never take out a patent on a new remedy or invention. These things explain in part why the average income of the physicians of Kentucky is less than \$800. It is important that the officials and people be informed of these facts that a misconception of the purposes of the profession may not obstruct this most unselfish work.

THE STATE HAS AT LAST DONE ITS FULL PART.

The iterated and reiterated opinion of President Taft, Mr. Roosevelt, Mr. Bryan, Mr. Wilson, leading senators and representatives in congress, educators, the press and others who mold public sentiment, and the emphatic declarations of both national platforms within the last few weeks in favor of a national department of health, show the growth of the movement in recent years. More important to us, our last two General Assemblies did more for the protection of the health and lives of the people than was done by all the others in the history of the State. It created a State Bacteriological Department, open free to every citizen, to assist in the early recognition of the communicable diseases, and to supply sera for their prevention or treatment; a Sanitary Engineering Department to supervise and aid in securing improvement in the water supply and sewerage systems for cities, towns and country homes; a Vital Statistics Department to secure complete returns and the uniform registration of all sickness, births and deaths in every county, and providing ample funds for operating such departments. No less important, provision was made for this annual school, with compulsory attendance, for the practical training of county and city health officers, with expert scientists and demonstrators from other States and the national departments, and our own members and officials, as teachers. That this school may be practical, an effort will soon be made to get the cooperation of the local authorities and make the sanitary conditions of some small city, and types of country homes near it, ideal as to water supply, sewerage, garbage disposal, street cleaning, school house construction and maintenance, dairies, bakeries, markets and the reporting and management of communicable diseases; with the appointments of the country homes complete for the promotion of health, so that the school

may meet there and use these as object lessons.

WHAT COUNTIES AND CITIES MUST DO.

As previous legislation had made the other health machinery almost perfect, upon paper at least, the possibilities for practical life-saving work in any county or community are only limited by the extent to which the local fiscal authorities and people will co-operate in it. For it should be known that even with this advanced legislation and liberality there is little promise in this field in any county or city which does not have a well-trained health officer, who can devote his entire time to the duties of his office. In order to make it easier to bring this about, and in the interest of both efficiency and economy, it is suggested that, except in counties containing cities of the first class, systematic efforts be made to combine the city and county health offices so that both may be held by the same person, having the law amended, if necessary, that this may be done uniformly. It should not be a political office and the tenure should depend upon the betterment of sanitary conditions as shown by a steady decrease in the sick and death rate. As no one can be a health officer of the kind for which I am pleading and practice medicine, the salary should be such as is given to circuit judges and other officials where a high order of capacity and unceasing devotion to duty are required. In fact, it would be just as reasonable to expect judges to support themselves by the practice of law while serving on the bench as to expect health officers to do their far more important and exacting work, requiring the highest order of training, skill and judgment, and practice medicine at the same time. After careful consideration, I would recommend that the salary of the health officer should not be less than \$1,200 in the smaller counties, and that it should be made \$4,200, that paid the circuit judges, in most counties. He should be required to devote his entire time to the duties of his office, and the salary should not begin until he has taken a course and obtained a certificate of his qualifications for public health work, gives his entire time to it, speaking and giving stereopticon and other demonstrations before schools, churches and public audiences until public sentiment is aroused to support the campaign.

Let us no longer deceive ourselves, or permit the people to be deceived about the matter so vital to them. Until we can have a health officer in each county and city so selected and supported that he can afford to fully qualify himself for it, and make the prevention of sickness his life work, most of what this board and the medical profession stand for is but an idle dream in that jurisdiction.

It should be known, too, that all of this is even more important to country people and those of small towns than to the residents of cities. Necessity forces the latter to some observance of the laws of health, and in consequence the preventable sick and death rate is lower with them than with the farmers, who ought to be the healthiest people in the world.

THE DUTY OF THE PUBLIC.

If time permitted, it might be interesting to discuss the elementary question as to whether the individual of the State should do any or all of this work. Between the socialist, who believes the government should do everything, and the individualist who believes it should do nothing, there is every shade of opinion. As usual, the truth lies between these extremes. There is much to be done by the individual citizen, but in the matter of health especially, even if he knew his full duty and did it, there would remain much which must be done under public authority or loss of health and life must result. For, after all, the government is only a great partnership formed to do those things which the individual can not do, or cannot do so well or cheaply, for himself. He can not hire a policeman, own a fire engine, build roads and bridges, or employ capable teachers for his children. Each partner, the citizen, is forbidden to do those things which would be injurious to others, and each pays a certain sum every year, his taxes, with which the government hires done those things that are necessary for the welfare of all, the protection of health and life being among the most important of these, as has been already shown.

THE PROFESSION HELPLESS WITHOUT PUBLIC SUPPORT.*

Can the rank and file of the people of the present generation be so aroused to the importance of this reform that local fiscal officials may be elected for cities, towns and counties who will provide that these benefactions of modern science be brought to every hearthstone? It is said that but one citizen out of every hundred has need for a courthouse except as a place of record for deeds, wills and similar documents, and yet they are taxed heavily to maintain these, with swarms of officials for these and other activities of far less importance than the preservation of health and life. For these and other reasons the intelligence and progressiveness of our fiscal courts and city councils are of far greater importance to the people than the qualifications of governors, congressmen and presidents. These bodies levy all local taxes, disburse the revenues and shape all policies and should be composed of the broadest and most successful business men, and we should go to the commission form of government if

necessary to secure the services of this class.

The medical profession has led this reform from a sense of duty, but is really less concerned in its success than any other class but, so long as the present order of things continues, and public and official sentiment demands that health officers and physicians shall devote their time and energies to the treatment of disease, the existence which is a reproach to our boasted civilization, this annual toll upon health and life must continue, and physicians can do no better than live upon the ignorance and misfortunes of the present generation and try to educate the rising one to better methods of living.

THE PROBLEMS AND DIFFICULTIES OF A HEALTH OFFICER.*

By M. W. STEELE, Corbin.

Many serious problems confront the health officials of to-day, and numerous are the difficulties with which we have to contend.

Chief among the problems for our solution is probably the question of how to arouse the public to cooperative action. It has been said that a lack of accurate knowledge on the part of the public in regard to scientific facts is the leading difficulty which confronts the progress of health work. It seems to me that the general public are very well informed in these matters, but are very indifferent and careless about concerted and proper action, and it must be admitted that some health officials are to some degree indifferent; but as a rule, there is a cause, for which the public is responsible, and which the public can remedy by co-operation and a sincere desire to give the health officer his dues. Therefore, action is what we need—activity on the part of every individual.

The people seem to lose sight of duty in their intense anxiety for individual freedom. In this particular matter the term "duty" implies a great deal to others who may be less assertive. And the public must be educated to respect this most important duty to their neighbors. Thus, while the problem is largely educational, it is not so much a question of scientific knowledge as of doing things and getting things done. The medical profession as a whole must awaken to a keener understanding of its responsibility to preventive medicine. I think that when a man accepts his license to practice medicine in a State that he should at once feel a sense of duty, to a high degree, to all the people where he locates, to do everything in his power to prevent disease. The health officer in the discharge of his duties, striving to prevent dis-

*Read before the School for Health Officers, Louisville, July 8, 9 and 10, 1912.

case, meets with many difficulties of increasing complexity, dealing not only with the material things, but with social and moral influences, and is liable to err through fear of offending some prominent citizen, and the arm which might have been strong for the protection of the public welfare has been crippled.

Prejudice surrounds the health officer, and there is always more or less selfishness with which to combat. Probably sometimes the medical men, through carelessness and professional jealousy, fail to rally to the support of the health authorities, when they are most in need of their support. I admire an unselfish and conscientious doctor even more than one of renowned ability.

To fully awaken the public to a more complete comprehension of their duty, we must insist upon the application of the Golden Rule. Personal interest of the few must be sacrificed for the good of all. A successful health officer must be very sympathetic and conscientious, but firm and determined in matters pertaining to his duty; being careful to do right, but determined to do his duty without partiality in spite of any influence which may be brought to bear. I pity the health officer who has not the necessary courage always present to do his duty, even though it may make him less popular for a time with a few.

The public owes it to us to help us create public sentiment. I fear that a great many ministers and teachers do not fully comprehend clearly the vast importance of the end toward which we are striving. But little progress can be made until we, as a body of co-workers, fully appreciate the relation of all measures to that end.

Tell those who may not know what science has done and is doing, telling it in simple terms, and explain that "science" is only another term for trained and orderly common sense.

The public must be made to think seriously on the cold hard fact, that health is the most important possession within our reach, and that it can be conserved and improved by simple means just as certainly and as accurately as any other asset, and that preventive medicine is by far cheaper than curative medicines. More should be taught in schools along this line, than is usually taught through the common school branch "physiology and hygiene."

One of the difficulties to be overcome is the prevalent idea among the laity that the burden of health work belongs to the medical profession. All the responsibility does not belong to the doctors. Our eager support of measures intended to safeguard humanity is very often misunderstood and misjudged be-

cause their honesty of purpose is questioned, when we indorse methods which, if logically carried out, will diminish our financial resources. I say we, for I am a practitioner, and must depend upon a general practice for my income, and am acting as health officer, for a pittance, as best I can under the circumstances until some better system of executive work can be perfected. I am very enthusiastic for public health protective measures, and I want to urge most strongly the need of special qualifications and the broadest and most thorough training for those who are to be made responsible for their intelligent administration; this done, one great problem will have been solved in preventive medicine.

Public health work has become a specialty which involves the necessity of a knowledge not to be obtained until recent years in medical colleges and universities. One serious difficulty of the health officials in some sections is the lack of power and authority. Those who are to be engaged in health work should be selected on account of their fitness and because they can command confidence. To them should be trusted the formulation of the work they are to execute. Sanitary ordinances should have the approval of the health authorities. If these authorities are not most competent to pass on such legislation they are not competent to serve in their capacity. It is illogical to place individuals in positions of trust and responsibility and to fence them in by suspicion or by inefficient laws, so that the successful carrying out of the work is impeded. "Responsibility without authority is farcical."

I hope to hear an earnest discussion of the problem of how to most easily interest people, of which there are a few in most all localities, who seem to know the danger of disease but who are wholly indifferent to sanitary precautions and are unduly self-conscious. In such cases it is sometimes difficult to apply legal action because of lack of cooperation on the part of court officials in making people do what they don't want to do for their own good. There are many unsolved problems, and therefore, a noble work before us. The prevention of pneumonia is one of the unsolved problems. Can we be idle when 150,000 of our people die every year of this disease. Many of us have accepted the position we hold from a sense of public duty—certainly not for the little compensation there is in it; but in spite of the many unpleasantness I have encountered I feel proud of the opportunity to do good for my fellow man, even though they do not sometimes seem to appreciate it.

The one great difficulty which confronts the active health officers is the lack of sufficient

financial support. Well trained health officers who are so badly needed must command good pay. Stricter laws are needed, the enforcement of which demands means to carry them out. The very poor and afflicted must be better cared for. These difficulties must be overcome, and will be overcome. The public are duty-bound in this matter.

Now that the dissemination of knowledge with respect to public health problems is so vastly important, let us not confine what we say on these matters to this meeting here in Louisville and to the medical press; but let it be heralded through the popular prints, and let us all carry a message to the people to every fireside in our territory if possible. Tell them the humanity and the justice of it all till they fully appreciate it, and our difficulties will be lessened.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By C. W. KAVANAUGH, Lawrenceburg.

Under the existing laws for the protection of the public against the spread of disease, begin the troubles of the health officer. The laws prescribe the duties fully. These include a supervision of all known diseases to which man is heir. To see that the whole face of the earth is clean, and unfit for germ life, that all water streams are unpolluted, that the food he eats is pure and unadulterated, and wholesome, that his whiskey is straight goods, that his cigarettes are free from opium, his quack doctors persecuted, and his patent medicines free from their coveted and potent agents, alcohol and opium. That he shall see that the vital statistic laws are enforced, that he shall have physicians to report to him all acute infectious diseases. There are many other side duties. The last duty I mention gives more trouble and annoyance than all the others. When a physician becomes health officer the war begins on him by the other physicians. They fire the minds of the people against all his orders. Dieredit his opinions. Say that he calls epidemics of scarlatina and nettle-rash, scarlet fever. Epidemics of Cuban itch and chicken-pox, small-pox. Epidemics of poison oak, measles. Epidemics of fits, cerebro-spinal meningitis. Malaria fever, typhoid fever. "Milk fever" puerperal sepsis. Strange to say that this state of things exists in intelligent communities. The first problem to solve is how to do away with this class of physicians.

The next trouble in importance is the salary of the health officer. This in the counties is left to the discretion of a unanimous

fiscal court composed of a political county judge, and over-honest ungristrates, the guardians of the public treasury, destroyers of graft. They regard every cent spent for the protection of the health of the mothers and babies as taken from their opportunity to cover up graft.

Over twenty-five dollars is regarded by these saints as exorbitant and outrageous for the yearly salary of health officer.

The law-making power of the State is actuated by pretty much the same principle as the county courts. They seize upon this as a theme to demagogue the people, aided by some ignorant and antiquated physician.

The last Legislature made itself the laughing stock of the enlightened world, by countenancing the investigation and attack upon the best Health Officer in the United States. He took this office in its infancy, and through trials and troubles, without scarcely any remuneration, raised it to the lofty pinnacle it now occupies. In any other field he could have been at the top.

How can this trouble be remedied, the problem solved? Only by the right kind of support from the profession to our present State Board of Health.

Another trouble of the health officer is the weak support of the secular press. This is the greatest power for good or evil in our land. Still its pages are crammed full of both religious and nonreligious, patent germ killers, preventives, and carping criticism of sanitation and preventive medicine.

Health column departments, full of misleading advice on sanitation and preventive medicine. Magazine articles, the fad of the day, describing to the public new discoveries in medicine, and the application of same.

Exciting and causing erroneous opinions in the minds of the laity and some of the profession, regarding hookworm disease, pellagra, and bubonic plague.

The last difficulty and problem is how to remedy these existing evils. I would suggest a State Department of Medicine, selected by the people, divorced as effectually as religion is from politics.

It seems to me our governors, our congressmen, and educated laymen are more ignorant of the science of medicine than any other class.

Our own "Champ Clark" has furnished the strongest endorsement of Electric Bitters ever given to a quack nostrum.

We shall never get adequate relief from the legislative body till the power of corporate interests and machine politics are banished and the "people rule."

Laws should be drawn up by educated persons, and those versed in the subject legislated upon.

*Read before the School for Health Officers, Louisville, July 8 and 10, 1912.

I believe in Germany all laws are formulated by learned professors. We shall never get a perfect medical law, that is slobbered over by the two by four legislative lawyer.

Lastly, you can have no effective law without money. The health officer should be paid a salary commensurate with his duties, and this should be fixed like the salaries of circuit judges of the State and not left to the whims and fancies of ignorant magistrates.

PROBLEMS OF THE HEALTH OFFICER.*

By BEN W. SMOCK, Louisville.

The subject assigned me is a large one, with many phases according to the territory to be covered, whether it be national, state, county, city or town, so I shall attempt to deal with the matter in a general way and hope to be brief and comprehensive.

To begin with, one of the difficulties of health work in a small community is the determination of the specific work to be performed with a limited amount of money. Many health officers complain that they cannot obtain sufficient money from their legislators, fiscal courts and city councils, and hence are handicapped in doing any work. The outcome is that little or nothing is accomplished. The reason for the inactivity is a *lack of appreciation of the duties and opportunity of the office*. The incumbent does not give sufficient study to the work. He does not realize how to produce the results which will be of the greatest good. He should do that work which will not only be of public benefit but of public instruction.

To dabble a little in several branches of the work in the great field of present-day preventive medicine is not the best method to convince the general public that the health office can be, and is, a great good in the community. It is not as convincing to the fiscal authorities as a single line of work pushed to completion. Where but a very small appropriation of money is allowed, the bulk of that money could well be used in a certain piece of work which would be of local importance. This sanitary work is developed as rapidly and completely as possible, with two objects in view: (1) It is the purpose to develop a health effect which will be of great good and of permanence. (2) The work should be of such a character and carried to such completion that the general public and men in authority who make the appropriation, are convinced that good results have been obtained with their money; that the work has been worth the while and the results are perman-

ent, and further, that with a greater amount, this and more effective work could have been produced.

It may be said by some that this is "politics" but it is the only kind of politics which is legitimate in public health work. It is not only done for the good of the community, but as an education of the people and of the fiscal authorities.

This education must of necessity be done simultaneously. If the people's money is used to dig a ditch to drain swampy land it is not sufficient to state that it is a prophylaxis against malaria; but the economic side of the proposition must also be presented to the effect that the digging of the ditch raises the realty value in that neighborhood; it drains dirty water, possibly sewerage (as does one in this county) it eliminates odors; it checks the development of mosquitoes; it kills out insect pests; it makes the screening of houses more effective; it makes the surrounding region more desirable for industry; and for the comfort of the home; it therefore increases the wealth, raises the health, and adds to the general moral uplift of the whole county. It is also a practical, permanent improvement and will cost but little or, nothing to maintain. When the public are told the above with the necessary explanations, they will the better realize that the ditch was well worth while, and the health officer has accomplished good; still all preventive medical work begins in education; that education to become effective should begin with those who may be of the greatest assistance; viz.: doctors, newspaper editors, (especially editorial magazine and newspaper writers) law-makers, teachers, preachers, business men, civic associations and women's clubs. The instructions should not be carried along one line to monotony, but a change of front and a variety of subjects becomes more acceptable and more convincing. For instance, in discussing the cleaning of streets and public roads, the influence of dust arising therefrom as a causative factor in developing tuberculosis becomes monstrously tiresome to the public. They would prefer to know what effect such filth have upon their comfort and household economy—upon their furniture and clothing—upon their milk and food supplies; upon their business and upon their reputation and prosperity.

If the appropriation will permit but an occasional cleaning of each street and road and sprinkling with crude oil, the whole community remains dusty and all suffer alike. If with the same amount of money the principal thoroughfares be kept scrupulously clean all the time, and all dust eliminated, the people can see by contrast with other roads and streets that the health department is effective where it is permitted to work.

*Read before the School for Health Officers, Louisville, July 8, 9 and 10, 1912.

Mrs. Caroline Bartlett Crane, the great woman civic worker, never uttered a truer saying than that "clean houses could not be found on dirty, dusty roads or streets."

If the money granted for a public health office is but little it seems unjust to the public for that money to be hoarded in a bank. Some health officers say that they have only a little money and will conserve it for a while. Bankers are not sanitarians.

Be the amount ever so small, if placed in efficient health measures there is a geometrical increase in dollars and cents, and then will the public invest more substance in their health office, resulting in more benefit to themselves; but this investment will not come unless actual results are obtained. Publish a report of the work done, results accomplished; be the office ever so small. Let it be shown how much of the health officer's time was required to accomplish the work and what so much time is worth to him. It should be shown that had there been more funds appropriated, more results could have been produced. Set forth the future needs of the local community in the order of their importance.

When it comes to dividing up the money outlay of a small health office there should be an allowance made for necessities; such as office rent, postage, stationery, transportation, salaries, etc. There should be set aside a small sum to cover emergencies and to be used in the control of outbreaks of epidemic diseases. It would then seem just to reserve much or all of the balance for developing one or more certain health measures which would be of the greatest benefit. These acts are of more or less local significance and must be determined for each individual community. They may be in reference to water, milk, foods, refuse—garbage, sewerage—street and road cleaning and oiling; various diseases, various industrial conditions or occupations; tenement housing; care of school houses; inspection of school children; care of the babies of the indigent; bettering the conditions of our county asylums, and since statistics are the bookkeeping of successful health work, provision should be made for a correct collection of vital statistics and the other necessary tablets which show the value and result of the special work undertaken.

Perhaps the chief impediment of effective work lies within the health officer. The health officer himself may be as much in fault as are his political backers. The dangers of the office are the political shackles; the hope lies in the ability of the officer to force an escape by measure of judgment—of ability—and absolute honesty and sincerity. Just as long as the office is used for advertisement—and for a living only—so far is the delivery

of the one from the other; when the officer for his meagre pay merely gives the people an opportunity to read his title on his letter-heads, when he waits for an epidemic to gain a foothold before starting work, the public cannot be expected to elevate his office or its salary; for a salary of one hundred dollars, he should do a little over one hundred dollars worth of work. He cannot be expected to devote all his time for such a pittance, but he should *earn what little* is paid him. The public is beginning to consider health work as a business proposition, and he who makes good and earns his salary is the first one to receive a raise. If a man cannot afford to devote the proportionate time which the size of his salary indicates, he cannot afford to hold the office. If he cannot afford to withdraw then he should not and cannot afford to draw the pay without work. Sincerity more than anything else, stamps success. There are many health officers who do remarkably good work; but the few who do not appreciate the importance and opportunity for good which accompany the office are the men who check the elevation of the work.

Frequently much time is lost in some cases due to the appointing power not being personally acquainted with the best man available for the position. It sometimes is a difficult matter to find the right man at the right time, but while search is going on it is often poor policy to let the people suffer and watch for action. This can easily be obviated by choosing an energetic, enthusiastic, skilled man in the city or county, or by accepting one recommended by national, state, medical or other well experienced bodies or authorities. Such appointments could be made temporary, or for a month or two. It is to be understood that the officer selected must of necessity make good. Should he make good, the appointment should be made permanent.

In small scattered communities the idea is not a health officer with a small salary in each city or town making no provision for the intervening country, but a county health officer having jurisdiction over the entire county, including all towns up to a certain limit of population. The officer should be selected by those in a position to judge of his fitness for the position. The tenure of office should be for life and the salary sufficient that all his time may be devoted to the work and that the position will become so desirable that men, good men, will become specially trained for such duties.

It is patent to everyone within the sound of my voice, engaged in this great work of conserving public health, that the key to the whole situation, the solution of the whole problem, is hard work and must be wrought with brain, brawn and money.

SOME OF THE DIFFICULTIES WHICH BESET THE LIFE OF THE COUNTY HEALTH OFFICER.*

By HUGH D. RODMAN, Bardstown.

First: The people, who have never caught on to the benefits of improved sanitation. Everything, with many of them, which is suggested by the medical profession is opposed, on the grounds that it's 'no good, we've always gotten along without this foolishness. Our fathers and grandfathers didn't do these things, and they got on all right, much better than we do now. This fellow thinks because he is health officer he must make himself conspicuous.'"

These and a thousand and one other objections are thrown into the teeth of the county health officer. But let your neighbor build a pig-sty close to your door, or dump the putrefying carcass of a cow within range of your olfactory organs, and within the twinkling of an eye this same chap who has been ridiculing the Board of Health and its health officer, will rush to the nearest telephone and call up the health officer. Some thing like this: "Hello doctor, ain't you the board of health?" To which the doctor answers politely, "Well, no, I am not the board of health, but I am a member of it, what can our board do for you Mr. Jones?" In great excitement he answers: "I just want to tell you that Sam Brown has hauled a big dead steer just across the lane from our front door and it stinks so that we can't eat nor sleep for it, can't you do something to stop the stink?" All at once it dawns on this health officer that just a few days ago this same Mr. Jones was saying everything he could to render the health officer's work useless, but this recollection of his unjust criticism must not now influence his conduct. He must be a courteous and polite gentleman and answer Mr. Jones politely and assure him that he shall have relief.

Let a case or two of small-pox develop in your county, and, oh! what a buzz and a hum among the people; what a cry for the health officer! What's he doing? Why don't he put a guard around this house? Why don't he stop these people from running on the streets? And many other such exclamations.

And if the health board or its health officer does not handle the situation just to suit Tom, Dick and Harry, an indignation meeting is held, a resolution is adopted calling on the State Board of Health to dismiss the county health officer. This much "cussed" man stands meekly by, like the lamb in the slaughter house and witnesses the butcher sharpen

his knife preparatory to the slaughter. When the temperature of the gathering begins to subside and order is restored in the meeting, the health officer exclaims; "Thou fools you know not what you do nor whereof you speak. If you would entertain and express more confidence in your physicians generally, and your health officer especially, who are laboring daily, yea hourly for your well-fare, you would display a greater spirit of gratitude and more practical common sense than by such conduct as this. Your physicians, whether in private or official capacity, are entitled to your confidence and merit your assistance and approval in their efforts to protect you against contagion. Your board of health works gratuitously and its efficiency speaks for itself. Not in thirty years has your board of health, through its health officer, failed to promptly suppress an outbreak of small-pox. Your board's representative is ready, willing, yea anxious to do all that can be done for your safety. Give the health officer and his associates your hearty approval and your active support and you need have no fear. But if you people handicap us at every turn, how can our work succeed.

The second great difficulty, and in my mind gentlemen, the most insurmountable one, is the want of means, the want of money. The time has come when nothing can be accomplished without money. Money! Money, Mr. President sets a-hum all the wheels of machinery; all the power of the world for both good and evil is controlled by money. Money is the moving power of the world, and without it nothing is done which is done, and the county health officer has no money; he is a poor boy, and the fiscal court won't give him any money nor pay his legitimate bills. The fiscal courts in many counties are a drawback to the health officer in the successful performance of his duties. First the salary which is paid many of the county health officers is wholly inadequate. A doctor who has anything to do can not give his best attention to the public good for a mere pittance. In my county, Nelson, which is above the average, both in area and population, the salary is \$150.00. Our fiscal court pays no heed to the recommendations of our board of health; refuses absolutely to pay any bill which is contracted by the health officer unless he has an order from the county judge, made in an open term of court. Our fiscal court gives our board no encouragement and no assistance. I say our board of health instead of our health officer, because our board of health and our health officer are in perfect accord, and act as one man. If the whole people can be made to realize that every act of the county board of health and its executive officer is unselfish, and for the good of the whole people

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

ple, although at times it may cause some little inconvenience to a few individuals, and the fiscal courts could be educated up to the fact that a little money spent for the protection of the health and lives of our people, is well spent, then and not until then will many of the difficulties which beset the county health officer be removed and his pathway be made more smooth.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By A. V. MENESEE, Williamstown.

Conscious of my inability to deal adequately and comprehensively with a subject of such far-reaching import, of such recognized and supreme interest to the community as the one which has been assigned to me on this occasion, I must confess to no small degree of trepidation in approaching the task.

Professional occupations have left me too little time to arrange my ideas, at best somewhat floating and nebulous, in a systematic or logical form; and I doubt if nature has conferred upon me even a moiety of that literary talent which might lend color and charm to the discussion of so serious a matter.

Circumscribed by the limits of a small town, in a county of less than fourteen thousand inhabitants, and senselessly occupied with the countless details of a general practice, my experience and the trend of my studies have not been such as to enable me to speak either with special knowledge or academic authority upon the problems and difficulties which surround the lot of the modern health officer. Therefore, I shall be content to touch merely upon the fringe of these important questions, soliciting from you in advance all possible indulgence for my shortcomings and whatever patience you can command toward the rude and unpolished expression of my views.

The function of the health officer has grown in dignity and consequence just to the extent that advances have been made in pathology and etiology. The progress and future of hygiene among the people at large depend upon his intelligent activity—upon the knowledge and tact which he brings to the discharge of his official duties. The study of the causes of disease, the formulation of rules for their removal and prevention, being the substance of his obligation to the public, he naturally becomes an indispensable, if an humble exponent of that great science, of preventive medicine, which numbers in its ranks so many illustrious and learned men, and which stands foremost, among the achievements of our

civilization, for the moral uplift of society and the amelioration of human wretchedness, degradation and crime.

The establishment by law of a system for the preservation of health, for the enforcement of cleanliness in municipalities, for the regulation and control of contagious disease, and for the supervision by accredited officers of these conditions, is a vital part of our national and state policy. It would be a singularly unhappy circumstance if we did not, here in Kentucky, keep pace with the best thought and the best endeavor now being expended in the states about us to bring to perfection this noble and beneficent institution.

Speaking of those health officers whose sphere of labor lies measurably in the back eddies of progress, in an environment where they encounter much derision from the mob and little sympathy from those who ought to be most active in furnishing them comfort and aid, I would suggest that they have an infinitely harder task and much more difficult problems to confront than any other class of men engaged in the same kind of work. The rays of encouragement from the law-making body and their reflection by the local authorities have been far too scarce, and the review of their past accomplishments, in many sections at least, can never be of a rosy, or even very helpful character. The work has been going on for some years, under miserable disadvantages and with dreary monotony, though developing now and then remarkable results, and many instances of individual devotion to ideals at the cost of self-sacrifice and hardship. It might have been hoped that by this time, the sun of enlightenment and prosperity would have looked out behind the clouds; but, it must be admitted that all is still rather dark in the direction I have spoken of. It is certainly depressing to observe that, in some counties, otherwise progressive and rich, the chief health officer's salary is fixed at the miserly and pitiful sum of an hundred and fifty dollars per annum, a sum manifestly insufficient to meet his ordinary travelling expenses were he to discharge the duties of his office in proper fashion. And yet the same communities demand an expert's knowledge upon the part of their health officer and judge of his actual performances according to the highest standard of efficiency, although they do not hesitate to deny him a just and reasonable compensation for his services. Money spent upon an undertaking so intimate and essential to the whole body of the people, under wise administration, is indisputably not wasted; it cannot be rightly called extravagance; and no one could truthfully say that the expenditure was inconsistent with the most scrupulous econ-

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

only in dealing with the funds raised by taxation.

The tax-payer may insist on economy in other matters, on parsimony if he will; but parsimony here is folly, and if the people of these counties wish to hamper, obstruct and destroy a public enterprise of this character they are blind indeed. As long as they withhold a generous wage from their health officer, they virtually do this very thing; for they can not hope, by following such a course, to secure the services of really capable and scientific men. It is apparent that a physician in general practice, whose living and that of his family must come from his professional labors, would be at great disadvantage in allowing himself to be selected as a health officer on the salary usually provided. Not only would the duties of his office require a very large portion of his time, distracting his attentions from personal business, but the enforcement of sanitary laws being in many instances exceedingly unpopular, he would in all likelihood incur dislike and provoke enmities which might seriously affect his success as a practitioner. If they did not undermine his private fortune. This difficulty renders the present system more or less impracticable, and we can never have a satisfactory administration of our sanitary laws until we affix to the office of the health officer in each county such a salary as will justify him in devoting his whole time to its management. It were better that he should not attempt to do a general practice at all, but rather that he should confine his attention to the study and superintendence of all the cases that are legitimately within the purview of his official duty. The interests of the community lie in the choice of competent health officers and in the fair and liberal treatment of them; the interests of the latter lie in receiving a hire that the labor is worthy of, and the opportunity to do good work under good conditions.

In many localities, especially in those remote from the centers of refinement and learning, there is an almost incredible amount of superstition, bigotry and prejudice against which the health officer has to contend, and for the most part, absolutely in vain. It is amazing to what extent practicing physicians who ought above all others, to co-operate with him, either openly antagonize the health officer, or, by their gross negligence and indifference, hamper and thwart him in all that he undertakes to do. They often omit, sometimes they willfully refuse to report the first case indicating the appearance of contagious disease, and thus leave the officer in ignorance of its existence until many similar cases are developed, or at least until an appalling number of persons have been exposed. Again, epidemics of more or less severity, sudden-

ly break out, because the heads of families fail to make known, and not seldom deliberately conceal, sickness of a contagious nature. There is great difficulty at times in maintaining quarantine of patients in country regions where the people are stubbornly rebellious under this kind of restraint and where police assistance can not always be invoked, or, if on hand, prove to be listless and corrupt. Then, quite a surprising number of people fail to understand the importance of vaccines and antitoxins and grow obstinate in their refusal to submit to them at all. The health officer, forced to assume the responsibility of procuring obedience to these measures of discipline and treatment, is often visited with threats, and even in many cases, with attempts at actual violence.

Another obstacle which continues to vex the country health officer and stand in the way of effective work is the absence in so many counties of an eruptive hospital, ample in size and decently equipped to meet the needs of the community. There are many places where no provision of any sort is made in this direction, and many others where it goes no further than the construction of a small, rude frame building, of meagre dimensions, in some instances, containing only one room. Even these buildings are seldom used, or kept in a state of cleanliness fit for use, the custom not infrequently being to isolate patients suffering from contagious diseases, in their homes, in freight cars, and old out buildings. Upon the termination of the disease or the removal of the patient, such places, owing to their worn roofs and general bad repair, are not susceptible of proper renovation and disinfection, but remain as an eye sore and a possible source of further contagion.

If only moderate care be taken, the general health of a community can be fairly well preserved, but these conditions make it difficult and well-nigh impossible for the health officer to handle epidemic diseases in a satisfactory manner or to stamp out the seeds of contagion with any degree of certainty. The best ideals of method are beyond his reach because he is not supported, as he should be, by the mass of the people, and his enlightened struggle to put in practice the true principle of hygiene and preventive sanitation receives no material encouragement from those who are placed in control of the public purse.

The school-house overshadows every other institution in almost all small communities, and it is here, if anywhere, that the health officer should be allowed to exercise the full and reasonable authority of his office.

He ought to have the time and the opportunity to visit all the schools in the county, to take personal cognizance of the condition of the children as to their health or disease, to

see that they have a chance to breathe pure air, drink pure water, and enjoy cleanliness of body, in surroundings absolutely salubrious and free from the danger of communicable diseases.

The difficulty of ascertaining what pupils are tubercular and of excluding them, when ascertained, from contact with the other children of the school, is a very great one; but it is a matter of vital importance that this should be done, and that every facility should be placed at the command of the health officer for the immediate execution of his duty in this regard. Presupposing competency upon the part of the person intrusted with this work, the rigid application of these rules, based on the careful examination of each school, would, no doubt, greatly lessen the spread of disease, materially reduce the death rate, and vastly improve the average school-child both in point of physical endurance and in the exercise of his mental power. This is a consummation devoutly to be wished for the future, but we can not, so far as concerns many counties of the State, assert that it is an existing fact at present.

There are a multitude of points worth notice in any thoughtful discussion of the difficulties and problems which the health officer must encounter in the prosecution of his public duties—the difficulty and problem of dealing with the continuous depositions of organic matter where there is no water system, of fumigating and cleansing infected quarters, of persuading people to adopt general prophylactic measures, of breaking down the popular delusion concerning quack nostrums and proprietary medicines, of rectifying the filthy habit of expectoration in public places and other careless acts which lead to the propagation of some of the most dangerous forms of ill health and disease, of milk and meat and general food inspection, and of reducing to a strictly scientific basis the whole catalogue of preventive methods in dealing with maladies that can be specially and surely provided against.

It would be impossible to treat of these matters categorically or at any length within the limits of a paper of this description, and they are merely mentioned as indicative of the broadness of the field and the scope of the activity which, even in country districts, call for the exertion of high talent and unflagging energy upon the part of a trained, conscientious and faithful health officer.

The work of the health officer is, in all of its practical aspects, a continued warfare against those conditions of modern society and the negligent carelessness and indifference of so many people which still contribute to the production of zymotic disease and keep alive the morbid principle of contagion and epidemics

in our midst. That town, or county or state which fails to make adequate and just provision in its laws for so necessary and praiseworthy a factor in the preservation of its well-being and wholesome growth, lags lamentably behind the advancing ensigns of our race's humanitarian progress and moral regeneration.

A pleasing feature, in connection with this line of effort, is the recent law providing for a school of systematic instruction which health officers are required to attend. Such a school is much needed and denotes a forward step, but the course might with profit be made longer and no interest could be harmed by the grant of a reasonable allowance in money for time spent in attendance thereon, to health officers where salaries are so small as to render their attendance a personal loss and hardship. It is unnecessary to comment upon the propriety of this measure. The expectation that it will go far towards supplying the average health officer with the special knowledge requisite to the proper performance of his duties, will not be frustrated unless all concerned prove faithless and incapable; and the hope is well-grounded that it will inspire him with a missionary zeal to teach not only the people in general, but the physicians themselves how to prevent and wipe out disease. By public speeches, by newspaper articles, by school-room and church lectures, by the use of timely illustrations in the shape of moving pictures and other things, the health officer could accomplish more direct and lasting good to the human family than any other class of men within my knowledge. In the smallest towns, and in the most remote and ignorant regions, he could, by these means, convert his office which is now all too frequently an empty name and an unprofitable decoration, into one of the crowning glories of local government.

The march of improvement may seem slow; for prejudices, inertia, public indifference, and official jobbery—all entrenched in corrupt politics and sordid intrigue and enforced by the selfish ambitions and cold cynicism of men—are to be combatted, overcome, and demolished. But the outlook is fair, the beneficent promise of health and happiness to society which must arise from the fruitful labors of instructed men in this branch of the public administration will appeal to every thinking person endowed with an atom of imagination. This noble work can not go backward, it must go forward; and if a comparison be made between its present status and what it was only a few years ago, it will be not only seen that a substantial advance has been actually made in all that concerns its improvement and its expanding relation to

humanity, but that a momentum has been acquired in the march which will become more and more irresistible. If the difficulty here and the problem there has been great, if at times the one has appeared insurmountable and the other unsolvable, their final conquest will be all the more honorable and splendid. No prouder mission can any man enter upon than this to serve his fellow-man, to restore them to their original birthright, to health, sanity, a pure environment, and the happiness of well-ordered and beautiful lives—a mission as brave and as holy as that of the crusader who, in olden times, sought to rescue, in the face of famine and death, our Savior's sepulchre from the dominion of the paynim hordes—a mission enlisting him as a soldier of the great army which, employing all the weapons of science and learning, is to-day fighting to emancipate mankind from the thrall of pain and suffering and avoidable disease, and to make of the human body a temple unpolluted and sacred—a fit habitation for the immortal soul.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By J. B. KINNARD, Lancaster.

To aid in the conservation of health, to prevent disease and death, is the sole object of the health officer. The position is one of great responsibility where remuneration is out of proportion to the value of services performed. The pay usually received is in inverse proportion to the difficulties and duties imposed. The importance of the office is not fully recognized by either the profession or the laity. Into the hands of this officer is placed the responsibility of the prevention of epidemics that may devastate whole communities unless checked in their incipency. The failure to perform a duty may invite the spread of infectious and contagious diseases, resulting in numerous deaths and paralysis of business.

In 1873, Lancaster was visited by an epidemic of Asiatic cholera that could have been checked in its incipency had there been a health officer in the county. The disease was epidemic in the United States at the time, and when a man hailing from an infected district was prostrated with diarrhoea and vomiting in our midst the case should have been instantly suspected, isolated and quarantined. No steps were taken to warn the community. Carelessly, thoughtlessly or ignorantly, the dejected were thrown upon the ground, with no attempt at disinfection, where drainage led to a public well which furnished the water

supply to a large area, principally inhabited by negroes. From that case 54 deaths resulted. Business was paralyzed for two months and the city expended about \$5,000.00 for doctors, attendants and supplies for the poor and sick. Had there been a board of health, with an efficient officer, many lives would have been spared and business would not have been disturbed.

Some myopic, misguided communities, when infectious and contagious diseases develop, undertake to disguise the fact that an epidemic is prevalent in order to protect business, forgetting that lives are worth more than filthy lucre. The present greed for gain depreciates human life and exalts the god of Mammon.

Too often physicians fail, or refuse, to report infections and contagious diseases under their care lest they lose practice when such information reaches their clientele. Human lives have been sacrificed on account of such failures. They should realize that it is for the best interest of the attending physician the afflicted family and the community in general that infectious and contagious diseases be reported, investigated, and have proper surveillance.

In the suppression of nuisances, and probable and possible sources of danger to the community, the orders of the health officer are frequently resisted and disobeyed.

When I was appointed health officer many years ago I required notices of complaints of nuisances to be presented to me in writing and my notices requesting abatement were mailed. Now when I issue orders for abatement of nuisances they are delivered to the city marshal for execution. He is an ever present help in locating and abating any kind of nuisance. People pay little attention to a written notice, but when an officer visits them with a mild, but firm admonition, the nuisance is usually promptly abated.

Every man thinks his "right" to life, liberty and the pursuit of happiness" includes the right to do as he pleases regardless of his neighbors. Frequently pig pens and privies are placed in the most suitable location to offend the neighbors, and when attention is called to their dangerous proximity and the disagreeable odors arising therefrom, frequently become offended and resist the enforcement of the law. When the aid of the law is invoked they imagine they are being deprived of their sacred liberties.

In spite of laws against them some people maintain nuisances, but we have been partially successful in educating our citizens to obey sanitary laws and thus protect themselves and the community. The local paper has cheerfully and freely given space to articles upon the necessity of the observance of

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

the laws of hygiene and the enforcement of ordinances for the protection of the health of the community. The editors have cooperated with the board of health and the woman's club in urging the necessity of having a clean and healthy city and country.

A problem that has given me anxious thought is the building and caring for cesspools in small cities and towns that have no sewage systems. Where we have water systems without proper sewage cesspools are an absolute necessity. In my town we are having difficulties. We have a city water supply, the plant being owned and operated by the city, without sewage system, and consumers must dispose of waste either by cesspools or by discharging upon the ground. In either case difficulties will be experienced sooner or later. One suit has been instituted against the owner of a hotel in my city where a cesspool was made under the advice and direction of the State Sanitary Engineer, where the seepage, or overflow, was drained into an individual pipe line that discharged into a gutter in front of a restaurant on a back street. The cesspool was constructed upon scientific principles. I think the complaint is ungrounded and will so testify, but juries cannot be depended upon.

Where the limit of indebtedness will not permit some of the smaller cities having water works installing sewage systems the question of private cesspools must be settled in the near future. The pollution of wells and springs will surely follow the general installation of cesspools and damage suits will arise.

Now when a board of health, or a health officer, is consulted in regard to locating and building a cesspool, or anything that may prove a nuisance, will the advice of such board or officer render them liable? Or will the owner have to assume the liability? If the owner shall assume the liability why should he seek advice from the board or officer?

Another problem has been presented to me for solution. Complaints have been frequently filed to abate a nuisance consisting of a temporary pond located in a business section of Lancaster, occupying a position near the intersection of two alleys which divide a block into four sections. Facing the four streets which bound this area are several business houses, a flouring mill, poultry establishment, machine and blacksmith shops, warehouses, a church and several residences with this body of water in the rear of each. How can this mosquito incubator be drained? The elevation of the surrounding territory is too great without an expenditure of a large sum of money, to be drained. Until the Lancaster flouring mill was erected the natural drainage was through a sink hole which was filled and

cemented and now occupies the center of a large pool which was the sole water supply for the mill before water works were installed. For a long time the water flowing into this depression was drained into the pool, but since the storage pool has been abandoned the alley has been raised and the water is disposed of by seepage, but a considerable portion remains to stagnate. I have suggested, and the plan has been endorsed by the State Sanitary Engineer, that a cesspool be constructed at, or near, the lowest point of this depression and covered by iron grating to screen the debris. By excavating a few feet in depth a crevice in the underlying strata may be encountered that may quickly dispose of the sewage. Shall abutting owners pay for the improvement or shall the city do the work?

In this short paper I have presented a few of the problems and difficulties that have been met—some solved, some awaiting solution. In the future there will arise many difficult problems to solve and good judgment must be used by the health officer in their solution and disposition. This is the prophylactic age when an ounce of prevention is worth a ton of cure.

OBSTACLES AND DIFFICULTIES OF HEALTH OFFICERS.*

By J. G. FOLEY, Pineville.

These are many and varied, possibly the greatest one is, the lack of proper support, both moral and financial, neither the county authorities nor the people at large have hardly a conception of what is necessary or what should be appreciated for the support of a health officer in order to carry out only a limited sanitary move, and more especially in a county like Bell, where the county has never paid a dollar for the support of a county health officer or county board of health; yet they have paid thousands of dollars that might have been saved if they had had the right kind of a man for a health officer, and properly supported him, the moral support is equally as bad if not worse than the financial.

It is hard to make the majority of the people believe that a great many diseases are both contagious and preventable diseases, they still adhere to the old belief that they are hereditary conditions only, and I am sorry to say a few, and a few only thank goodness, of the medical profession still hang on to that old theory, just as they do that seven year itch can't be cured or stopped in less time than seven years; unless the poor devil who happens to have it dies, because it is seven year itch. They firmly believe if a

*Read before the school for the Health Officers, Louisville July 8, 9, 10, 1912.

father, mother, or other relative should die of tuberculosis, and a whole family of children become infected and die with the disease that would be perfectly natural and right, just as much so as for them to have blue, black, or brown eyes, or red, black, or brown hair, because a father, mother, or some relative had this particular color of eyes, or hair.

According to his actual size the common house fly is possibly the biggest and most difficult creature we have to deal with, he is like the poor, he is with us every year, his prevention and destruction is a matter of great importance, and yet the masses of the people pay but little attention to him in fact some think him a necessity, as he acts as a bureau of information, they can always tell when it is going to rain by increased number in the house and their tendency to hang on and bite just before a hard storm of rain, they too can tell as to the freshness of the milk and butter, as to whether or not the vegetables are nice and fresh, he does many other things too, but this is enough possibly to put some people to thinking.

Another obstacle is the indifference or lack of interest on the part of corporations and companies, this is especially so in milling and mining districts, where a large number of men are working, with but little or no attention given to sanitary conditions, with poor houses, defective and unsanitary closets and a polluted water supply.

The owner and controllers of such corporations and companies in a majority of cases are capitalists who live and spend their time in some summer or winter resort and make a demand on the local man in charge to show up why every day does not produce a profit on the investment, making no demands or paying no attention to the sanitary condition in which the laborers who have to produce this product live, or the kind of food on which they have to live. The health officer is expected to look after and right all these conditions, as that is his business.

DUTIES OF A HEALTH OFFICER.*

By J. W. KINCAID, Catlettsburg.

The key-note which will solve the larger part of the difficulties of the health officer has been sounded so often and so strongly by the various speakers of this conference that if it has not been caught by each one here, surely evidences the fact that he is out of harmony with the music of the march of progress, which has gained such momentum as a result of this meeting that it will go on with ceaseless tread until our State has gained the posi-

tion in health affairs which has been the dream and hope of that master mind of tireless energy and zeal, Dr. J. N. McCormack.

The key-notes are energy, enthusiasm and education.

Problems will be solved by the energy and enthusiasm of the health officer and the difficulties will be overcome by the education of the public and the cooperation furnished by it when informed and taught what they have to expect of an efficient health officer and what he has a right to demand of it. Until this education becomes general the health officer is confronted by a serious problem. How to do \$2,000 worth of work for \$100 or \$200.

Unless he has inherited a competency or married a woman with an ample dowry he is compelled to shut his eyes to conditions or view with complacency the situation while attempting to make a living from his profession.

When the State Board of Health was created, about the only reasons advanced for its existence was the fear of the horrible ravages of smallpox and that pestilential scourge yellow fever.

The money appropriated for the use of the board was pitifully small and inadequate, but in spite of the handicap of the lack of funds (which was due as much to the lack of knowledge and information, of the immense and incalculable benefits which would accrue from an intelligent campaign for better sanitary and hygienic conditions throughout the State) the work grew larger and larger, until now its purpose is not so much to control the spread of contagious diseases, as it is to make it impossible for them to exist, by a careful and constant watchfulness over the causes which make their existence possible.

To this end it has adopted various rules and regulations, which it is expected the various county boards will also adopt, and through their instrumentality and efforts render effective.

It might well be compared to the strategy board of an army, and the county boards to the army itself, and if its plan of battle (or warfare it were better called, because a battle means but one conflict, whereas their mission is to wage an unremitting crusade against everything which is detrimental to the public health) is to be carried out and forced vigorously to a successful issue, it must be entrusted to a *rank and file* whose courage, energy and valor will know no obstacles it can not conquer.

Hence it can readily be seen that the county boards of health, may become the strongest part of the machinery of the State Board and the county health officer being the executive of the county board, his duties can be as heavy or as light as his conscience and his activities

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

may make them. Laws which run contrary to the spirit and the inclination of the public are difficult of enforcement, and any law which curtails personal liberty is regarded by the individual affected as an infringement upon his rights. Hence, quarantine regulations, because of their irksomeness, are regarded with disapproval or disregarded entirely. To be effective they must be thorough, as the slightest break or laxity, may render everything negatory as does the smallest slip in the aseptic technique of the surgeon.

At this point comes in one of the difficulties of the health officer in making those concerned see the dangers of spreading a contagious disease. When you have convinced the parent of a child sick with diphtheria or scarlet fever that there has been carelessness, indifference or negligence upon the part of someone by reason of which their child is afflicted, and impress upon them their moral obligation to assist in the prevention of the further spread of the malady, there is seldom any necessity of invoking the penalties for violation of the legal obligation.

In several years' service as health officer I have but once found it necessary to institute prosecution for violation of quarantine.

Nor have I ever found it necessary to hire guards to make its enforcement effective even in cases of smallpox, relying as much upon the sense of moral obligation, as upon the fear of legal prosecution.

The greatest difficulty to be overcome by the health officer in his work is the ignorance and indifference of so many people along sanitary lines. If he is alert to his opportunities, in his daily walk, to do missionary and educational work, by preaching the gospel of cleanliness and citing the various rules of the State Board of Health as applicable to specific instances coming under his notice the general public soon begins to cooperate with him in his efforts, and while his work may grow heavier, it is accomplished with much less friction.

It was a common practice in Boyd county a few years ago to dispose of dead animals by hauling them out to some hollow not far removed from a county road which by long usage was called "bone yard hollow" and leave them there unburied, to become not only a stench in the nostrils of every one passing within a half mile of the spot but also a veritable centre of disease. If any objections were made it was only to the smell and not to the more obvious dangers of disease.

One nuisance noticed by our board requiring the offender to bury the half decayed body of an animal so placed, and the adoption of a stringent rule covering such offenses has completely eliminated the trouble.

It seems to me that there is an unnecessary

amount of work placed upon the health officers in the abatement of nuisances. The law should be so framed that when in his judgment a nuisance exists the health officer could serve a notice of abatement which would hold good if prosecution became necessary, without having to convene his board to so declare it.

The amendment enacted a few years ago making the county judge a member of the county board of health and having the fiscal court elect one member was one of the wisest things ever done. It has largely eliminated the difficulties and friction in the effective handling of smallpox and other outbreaks, and enables a tactful health officer to secure the material cooperation of the fiscal authorities in carrying out the reforms and innovations which in the light of modern knowledge are so necessary.

PROBLEMS AND DIFFICULTIES OF A COUNTY HEALTH OFFICER.*

By WALTER BYRNE, Russellville.

A physician is never more worthy the name than when he charms away a pain at a moment when it tortures most. It is then that he emphasizes most strongly the very indispensable nature of his calling. But in the consciousness of duty well done, let him not forget that his fullest service does not begin and end in the mere administration of the soothing dose.

Now when a health officer everts some threatened epidemic or by timely advice as regards the sanitary condition of some country school saves the eyes of more than a score of these helpless little innocents thereby saving them from a condition (total blindness) that is far worse than death, that the greatness of his calling dawns upon him and he stands like "a Colossus bestriding the world." If ever a man feels like a demi-god surely it would be after a duty well done and the good fight won against the evils of stupendous ignorance.

So gentlemen you see that something can be gained besides the meager pittance of a salary mostly allowed a county health officer. One of the greatest problems that faces the health officer to solve is how to get at the general public and interest them in their own betterment. The greatest difficulty that faces the health officer is "ignorance." How then are we, as health officers, to do these things? "The cleansing of the Augean stables" sinks into a small and insignificant task, when compared with the task of making the public believe that doctors, really and truly, want disease abated and stopped. The

*Read before the school for Health Officers, Louisville, July 8, 9, 10, 1912.

general public says "it's agin natur" to believe any such thing. Why, how will "doe" live if folks don't get sick? Where will "doe" get his good clothes and horses and automobiles and things? No sree; you can't fool your uncle Rube that away. But in spite of all this we are progressing and we must buckle on our armor and go after them again and again. Make it your business to talk with the school teachers, the ministers, the old ladies, the newspaper men, and the politicians, you will find the teachers ready and willing to aid you; the ministers will do their part, and the old ladies, God bless them, will aid you more than all the rest if you can hit them at the psychological moment. Because you fail to see results at once, do not despair, be assured that much good will come from your sowing.

Only a few months ago at one of our county meetings I talked to one of our old doctors, and he told me of the many sanitary changes wrought in the past twenty years in his community. How even the negroes were learning to dispose of the sputum in tuberculosis and other excrements in times of sickness. Truly the world does move. The ignorant whites are our most trying proposition; they are suspicious and envious and without ambition, satisfied with their lot in life, and jealous of their rights. Any interest you may show in their betterment excites suspicion; any attempt to coerce them into following out sanitary laws meets with stubborn resistance and open rebellion.

These, gentlemen, are some of the problems and difficulties that every health officer meets. Now, how to meet them and consider them.

Go with cheery word and kindly deed, in and out, among these people, telling them of the great and positive good done by sanitary experts in the army, in the city, and everywhere they go. Urge the medical fraternity to talk sanitation in every house they enter. Buttonhole your friends, the lawyers, the ministers, the merchants, the railroaders, "the butcher, the baker, the candlestick maker," and everybody, and talk and talk sanitation. Get the children interested, and get them to talking of "the deadly housefly," the "stegomyia fasciata" the "anopholes" etc.

We have got to educate these little ones in hygiene and in carrying out the laws of sanitation, if we want to get our State in a perfect sanitary condition, for it is as hard to educate the ignorant class of white adults in hygiene, as it would be to get them to understand Greek and Latin. And the only way we will ever accomplish the good that we should in the sanitation of our State, will be by educating the children in hygiene. We should have a class in hygiene in every grade of our graded schools, and children should be re-

quired to pass an examination on this subject before they are allowed to advance to the next grade. There should be just as much stress laid on hygiene in the schools as any of the other subjects. If we can get the little folks interested in a sanitary movement, they will be able to do more with the old folks at home, than all of the doctors in the State.

So let us see that every school in our State has someone that can teach hygiene among its faculty, and see that the children are taught hygiene and taught it well.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By T. ATCHISON FRAZER, Marion.

This is so large a subject and needs so much careful study that I feel my inability to grapple with it in a way worthy the subject. There are many angles from which we may view this matter, and we will endeavor to take the most practical course in its study. I will speak more from the standpoint of the rural health officer, as I am from a rural county, and my experience has been along that line. The problems are so many and varied that I hardly know where to begin, or, when to finish; but the first problem before all health officers is to save human life; to prevent such diseases as we know are preventable; to save the fathers and mothers, the boys and girls, and the infants in their mother's arms from a premature death.

We know in this beloved State of ours that between forty and fifty per cent. of the lives lost in the good year 1911, were sacrificed on the altar of ignorance and indifference, that their loss was a tremendous economic loss to the State, that the money spent for doctors, nurses, and medicine was money that should have been put in the regular channels of commerce. I will ask your pardon for my reference to the economic loss at this time. I believe it is important to get the people to look at the loss of money first, as the people of this country are primarily a commercial people, and it seems impossible to get the American people to look around the dollar to see anything, you must get the dollar before them so that they will have to look through it to see the object of this work.

The first great problem of the health officer is to qualify himself for this work, to understand the preventable diseases, and to know how we can meet the onslaught of this enemy when in its incipency. This school organized under the laws of the State will do more to educate the health officers of Kentucky than

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

anything that has been done. I want to congratulate the people of Kentucky for their wisdom in electing a Legislature that has the physical welfare of our citizens so much in mind as to enact a law that would compel the guardians of the public health to in some measure at least qualify themselves for this great life-saving work. If we take the interest in this, the first meeting, that it is our duty to do, we will go home to our people with a message that will bear fruit in the future.

The health officer to do the best possible work should be paid a salary commensurate with the work that he is to do. He should be in a position that he would not feel under obligations to any individual in his community; then he could have the support of the medical profession, which he so much needs in his work.

The one great problem of the health officer is to educate the people up to a good general knowledge of what the preventable diseases are, and how to prevent them. We should teach the people that typhoid fever is a disease that is bred and born in filth, and that no one can have the disease without swallowing some of the excreta from a typhoid patient's bowel or kidneys. We should point out to them the ways that the disease can be prevented; we should show them how the army surgeons prevented our soldiers from contracting this disease while they were camped on the Texas border in the summer of 1911. We should point to Panama which was once as deadly a place for human habitation as the "Black Hole of Calcutta," and tell them how the death rate has been reduced until it is now lower than the lowest of our American cities.

The "great white plague" is the most widespread of the preventable diseases, and it takes a greater toll of human life for its grind than any other disease.

Again education of the laity is of first importance for the tuberculosis bacilli can only become active when it finds suitable soil to reproduce itself in. The germs are expelled from the lungs of the poor victim, and find their way to the lungs or other parts of the next victim by entering into some open port of our bodies. The greatest difficulty in checking its ravages is the controlling of the "hunger" who roves over our country like some savage monster seeking whom he may devour. He spits on the streets, on the floors, in the public buildings, or anywhere he happens to be at the time he has to expectorate. He drinks from the common drinking cup; communes in our churches; coughs in our faces and sends the germ laden spray into the air that we breathe. As a rule he is not to blame, but the crime in most cases lays at the door of the doctor that is too selfish to run

the risk of offending his patrons; or he is ignorant of the principles of preventive medicine. Often he does not inform the patient, or family, of the nature and infectiousness of the disease until it is well advanced. In my opinion every consumptive should be under the supervision of the health officer. Diphtheria, measles, scarlet fever, and whooping cough all take their toll of infants and children, and the problem before us in preventing these diseases is to get the cooperation of the family physician to have an early diagnosis made, and a prompt report to the health officer so that he may take the proper steps to isolate the patient.

Dysentery and the diarrheas of infants and children are purely preventable, and I will assert that they are the easiest prevented of all preventable diseases if the mothers of our country are properly educated. There is no scene more pitiful than the wasting away of a sweet babe suffering of the so-called summer diarrhea that many mothers think is almost a necessity during the second summer; the little fellow pale, and emaciated, fretful and peevish; his skin hanging in wrinkles, his little bones almost protruding through the skin about the joints; his eyes dull and his features expressionless, his wail is pitiful as though pleading for help. The great problem in this disease is to teach the mother that the best way to treat this condition is to prevent it. The sweetest music that ever played on the auditory nerves of man or woman is the prattle of a healthy, happy baby, and it should be our constant endeavor to prevent the diseases that make these little innocents suffer during the second summer of their existence at the very time when they should be in the full enjoyment of baby life.

One of the problems for us to consider is the apparently mysterious disease, cancer, when we consider that about ten per cent. of all deaths after the age of fifty are due to this one disease, and that we know but little of the means of its prevention, it then becomes one of the great problems for us to solve, and we hope that in the near future some man will rise to meet the emergency, and tell us how to prevent this disease.

Yellow fever has been eliminated from our country, and it will be impossible for it to get another foothold if that eternal vigilance is adhered to that is necessary to our health and happiness.

We know how to prevent malarial fever but we are not making the progress along this line that we should. We have the means at our fingers ends to stamp out this disease, but, yet it is a problem for the health officer as how to apply the means to attain the results desired. This is a matter of education, the people must be taught that they can only have

malarial fever after being bitten by an infected mosquito, and when we rid the community of the mosquito we will have the prevention of malaria solved.

Pneumonia, lagrippe, bronchitis, and common colds are also in the category of preventable diseases and deserve our most careful study. The medical profession in general and the health officer in particular should be on the alert to teach the people the proper care of the air passages, and thereby save the sickness, suffering and deaths that are caused by these diseases.

The venereal diseases are very prevalent in this country and seem to be on the increase. Their far-reaching effect and influence are just now being appreciated by the physician. The layman seems to be in perfect ignorance in regard to these loathsome diseases. The microscope has revealed to us the horrible effects of venereal diseases on the innocent women of this country, and the bacteriologists are now in a position to say to us that about seventy per cent. of the women who undergo abdominal operations are forced to the operating table on account of venereal diseases, yet gonorrhea and syphilis are more often treated at the corner drug store than in the doctor's office. These diseases are treated as a joke by most young men who have not the least conception of their direful effects.

Blindness, the worst of all afflictions, is also a problem for the health officer to solve, and when we think what it means to be blind, and the facts confront us that ninety-five per cent. of the blindness can, and should be prevented this becomes a very large problem. Again venereal disease plays a very important part. Here again we may well consider the economic loss for ninety-seven per cent. of the blind become a charge on the State or the community in which they live.

There are many other diseases that properly come under the head of preventable disease, but it is not in the province of this paper to touch them all.

One of the great problems that is before us is the destruction of the common house fly. This pest is also a product of filth, and he is not satisfied anywhere else except at meal time, when he likes to eat at the first table, then when he has enough he will crawl over the things you eat, or get in your milk or coffee. I am sure that the fly is the carrier of at least forty per cent. of the germs that produce the sickness we have from the 1st of June to the 1st of October. The great question then is to eliminate the fly, and this can only be done through an enlightened public, therefore it is up to the medical profession, and especially the health authorities to educate the laymen. We should teach the people that screens in the windows will often keep crepe

off the doors. That food exposed to flies means that the food will be contaminated by pathologic germs that will surely produce disease.

Among the problems that confront the health officer is that of ventilation. The schools and churches of this country are notorious for foul, stuffy air. There are in every community many hidebound, moss-backs that think fresh air is poison, and when even a window is open, they will close it for fear of "catching cold". Children are kept in a close, stuffy schoolroom for two hours, breathing over and over the same stale air, and inhaling the same stale fumes that are in every school room, and then their parents will wonder why John or Mary has a cold. Sunshine and fresh air are absolutely necessary to the well-being of child life, and in this, as in all else pertaining to the prevention of disease, education is the key-note. Fresh air and sunshine will paint the cheeks with the rose tints of health, and make life one bubbling, rippling stream of happiness.

The question of food and drugs also should be considered one of the problems for the health officer to solve. It is a notorious fact that the men of commerce in this country will, in their greed for the almighty dollar, poison the women and children with chemicals they put on the market for people to eat. It is alright for you to eat benzoate of soda and salicylic acid if you choose but you have no moral right to feed them to helpless children. Foods that need chemicals to preserve them are stale and unfit to eat, and it should be a penitentiary offense for them to be sold. Rutledge Rutherford is the leading authority on food poisoning, and he estimates that six hundred thousand people in the United States are poisoned by foods every year and of this number many thousands die. We also know that drugs are put on the market and recommended to cure all the diseases that human flesh is heir to, that have no merit other than to relieve pain, and fix the opium habit upon the unsuspecting victim. Thousands of infants are sent to their graves every year from the effects of opium in soothing syrups. These poisons are given by loving mothers who are ignorant of their direful effects. The so-called headache tablets and powders that you find in every drug store owe their efficiency, if you will pardon the expression, to some of the coal tar derivatives. People can be found in every community who are suffering from chronic acetanilid poisoning, and yet they continue to take these drugs. The worst feature of all poison-carrying medicines is that they are labelled harmless.

The difficulties of the health officer are many and varied, therefore, we can only mention a few of them. One of the difficulties

that confront the health officer is that our laws are not adequate. There is not the proper means at hand to combat disease. The fixing of the salary of the health officer is in the hands of the fiscal courts of the various counties of the State, and not many magistrates are sanitarians, they as a rule have very little knowledge of the duties of the office. They do not appreciate the importance of the office; they do not know the necessity of clean premises, pure water, and fresh air. They do not know that lives are being sacrificed at their very doors on account of their ignorance. And, if I was going to give the paramount difficulty of the health officer, I would only say ignorance and superstition.

One of the greatest difficulties that confront us is the indifference of the people in regard to the cleanliness of their person and premises. They do not realize that it is to their interest to keep their bodies clean and wholesome. Many people who tolerate filth themselves think it none of their neighbor's business, but it is, no man has a right to maintain a nuisance that is offensive to his neighbor, for we are truly our neighbor's keepers.

The question of water supply and sewage is also one of the difficulties that we have got to confront, and it is a very large question, too. In the smaller cities the question of sewerage is one that is hard to solve for here again the hide-bound moss-back tries to obstruct our course, and we all know it takes money to install sewerage, and the vote of the staid patter counts as much as that of any one else; but the only course to pursue is to tell the people that it is for their wives and children that we are working, and that we are going to keep everlastingly after it.

One of the difficulties that confronts us is opposition. We meet it on all sides if we do our duty. If we do not meet with opposition it is a sure sign that we are doing nothing, for it is a well-known fact that all progress meets opposition, and that if we stand still or retrograde there is no opposition. Another difficulty is that we are afraid that we will make mistakes. I want to say just here that the man who makes no mistakes makes nothing. In conclusion I will say that I have only touched the high places on this subject, and at times have not stuck to my text, but it is impossible for one to cover this entire subject in one paper, or in one meeting of this school, as there is always something left unsaid that should have been told.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By J. F. Young, Monticello.

Since this is a new branch of work for the medical profession, perhaps, the greatest independence will be allowed.

Then I shall discuss these questions from the viewpoint which has been forced upon me from the environments in which I live and move and labor.

During the years, since 1907 as health officer of Wayne county, my study and observation of these practical health problems has fully convinced me that theoretically, the county health officer is in a position to be the most important unit in the health organization of the State, but practically this is not the true condition of the situation.

It is not because the county health officer is incompetent; it is not because he is unwilling to do his full duty; it is not because he does not appreciate the great good that he may do; but it is because of factors direct and indirect which he can not control.

Some of these causes, some of these factors, I hope to develop.

Each one has some problems and difficulties peculiar to his own locality, as well as the more universal conditions which apply to all alike.

Some of these conditions are the direct cause of the health officer's usefulness being reduced to the minimum.

There is no intention or desire, in what I may say, to offend any one, but if what I say carries with it a friendly criticism, it is hoped that some one will be led to think better in this new field of endeavor.

That I may bring out my first problem clearly, I will draw a contrast. Nine-tenths of all the buildings in Monticello have been constructed since 1898. They are new and modern in architecture. Plate glass windows beautiful in design and arrangement, make our prosperous business houses attractive; the mills are doing a good business; the two banks are modern in appearance, in business methods and are well filled. The graded school, housed in a modern brick building, is managed and taught by eight well-equipped teachers, first class and cultured. Three good church houses are in the town; cultured and broadminded pastors preach to an intelligent people.

About fifty per cent of the side walks are well paved with brick or cement. The professional men are capable and deserving. A citizenship not surpassed by any city in Ken-

*Read before the school for Health Officers, Louisville, July 8, 9, 10, 1912.

tucky. Tulips, hyacinths, roses, cannas on the lawns add to the charm.

Electric lights gleam out across the darkness in the early night to make the day longer for work or play. This is the reception room and is what may be seen when one comes into town.

There is another picture not so bad, I hope, which many small towns present, but these conditions can be changed and in so doing the breeding grounds of death-dealing germs will be destroyed.

Sure, I would not draw this indictment against Monticello, it is some other fellow's small town and village I am now telling about.

Walk with the health officer some hot day through the back alleys, through the narrow back ways, behind the business houses, and through the back yards of the homes. You will find a problem for your spare time there. Goods boxes and barrels and kegs are there. Oyster cans, fruit cans and beer bottles are there. Old rusted buckets and pans and broken stoves are there. Old broken crockery and queensware and bottles are there. Old hats and shoes and rags are there. Old dead cats and rats and mice are there. Pig pens and cow sheds and stables are there. Stagnant pools of water and decaying vegetation and growing weeds are there. Soap-suds and dishwater and kitchen garbage are there. Heat and sunshine and rain are there. Poison gases and foul air and offensive odors are there. Great swarms of flies and millions of germs of disease and winds are there. Sickness and disease and death are there. This is the old curiosity heap which is so many times allowed to form through carelessness or neglect and the winds and the flies carry the products of these places into the homes of the rich and poor alike; into the reception room, into the living room, into the sleeping apartment, into the dining room, onto the table and onto the food.

The health officer may have gone before the city council and pointed out these conditions and asked for an ordinance to have all this heap removed, carted off to some select place and these places made sanitary; still the material remains month after month just the same, unremoved.

This condition is not found at every home, the premises of one may be clean and beautiful in every spot, but this does not protect the home so long as these unsanitary conditions are allowed to exist on other premises; this fact makes it a public question and is of vital interest to every man, woman and child.

One vital question then which is of paramount interest to every citizen is, what to do with all this waste? There is only one answer: Remove all this heap of rubbish and make ev-

ery spot clean. Put in a well constructed sewerage system to carry off the waste. Put in water works, which will furnish an abundance of pure water at all times. We can not fight diseases successfully without pure water. This is the first and the most essential problem that every community must meet.

The conditions are such, that in many places the people stand in immediate and great danger of an outbreak of any of these fearful diseases of germ origin.

Day by day, and month by month, the soil is becoming polluted and diseases which were not described in our text-books a half a score of years ago are now among us.

It is only because of the skill of a number of medical men employed by the Government that other, more fearful diseases from foreign shores are kept out of this country.

Our motto should be at all times and at all places, "Clean up and keep clean." The water supply is not only a local question, but a State and National problem and needs county, State and National supervision.

The streams of the State are being polluted from their source in the mountains, through the State and throughout their course to where the broad river sweeps into the Ocean.

These are questions which every generation must meet and the more dense the population, the greater will be the necessity for their correct solution.

When any form of contagious or infectious disease gets a start in a community, the health officer can be of very great service to that community, if he is loyally supported financially; so that he can give all the time to the work the case demands. To make his work successful he must also have the cooperative support of public opinion.

The disease may be of such a character and so located that a quarantine must be established. This should be done in such a way as to make the family as comfortable as possible consistent with a thorough and efficient quarantine; at the same time there should be as little obstruction to travel and business as is consistent with efficiency.

Here the officer finds his usefulness very much crippled and his work much delayed, because there are no funds set apart that he can draw upon to have the work done promptly. I consider this the broken link in the work of preventing sickness in the State of Kentucky. With our present definite knowledge of the cause of diseases, we know that much of the sickness can be prevented, but it takes men's time and money.

The office of the State Board of Health has been provided for in a way that its influence for good is being felt all over the State. The county health officer is provided for in such

a way, that practically, there is no health officer in some of the counties.

We must go before the fiscal court for this officer's salary. This is one of his indefinite problems. The members of this court in some of the counties are men who are in sympathy with this officer's work and they are ready to cooperate with him and have thought correctly along these lines. They have formed some definite opinion as to the value of the officer's time and service, and to some extent pay him a sum commensurate with the value of the service, and are not willing to rate a medical officer's time and service with the common day laborer.

This is not the situation in all of the counties. Some of the fiscal courts have men, who are members by political chance. They may be good men, (and in most cases are excellent men), but they know nothing of what the medical organization of the State, and its branches, the county health officers, are doing and trying to do for the citizens in preventing sickness.

By their environments and education, they are led to believe all doctors' bills are too high and go so far as to lobby with the members of the court to put the health officer on pauper wages, thereby reducing his usefulness to the minimum.

To my mind it is simply preposterous, why a fund can not be set apart for the county board of health for its use in the work of sanitation, as the State has set apart a fund for the work of the State Board of Health.

A board of doctors, by their education, by their technical training and knowledge of disease producing germs and their mode of life, are better judges of when and how funds should be used for this work than any other class of men.

The very nature of this work is such; that the fiscal court does not know the value or the far-reaching results of a few hours time of the health officer; he may, and often does, shut up some contagious or infectious disease and never let it spread beyond the first case.

The people do not recognize, or know, the value of the services of a few hours spent in stamping out a disease. You cannot see the fire after it has been extinguished. Let the disease have its unobstructed way and scores of cases may develop and a number of deaths follow.

The county health officer can not give to this work his best time under these circumstances. There are definite and well-recognized causes why this is the state of public opinion.

Scientific medical literature and sanitation have never been presented to the people in a way to mold any clear and well formed opinion on these subjects.

There is not a great daily newspaper in any city in any country devoted to the laws of health and preventive sickness which go to the people at large. It is true there are great medical journals in many cities in every civilized country in the world, but they go to the physician, only, or at most to those who are in some way connected with the physician and his work.

Then another cause of this indifference is the very fact that the patent medicine people, the street vender, charlatan and hoodoo man keep themselves constantly before the public, through posters, through pamphlets, through almanacs and through the public press. This is the only printed matter a very great number of people ever see or read, about medicine.

We do not wonder then, under these circumstances, why there is no well-defined and clear understanding of these problems. Sometimes very prominent people in every walk of life will allow their names to be used in the public press endorsing these methods.

Who ever heard tell of a great surgeon saving the life of many each year, or a physician using remedies of known potential power, through a long and busy life, putting up posters over the town or paying for column after column in the city daily paper, telling of his work.

We are creatures of our environments and education and if our education has a bias in it, our conception and view of many problems may be warped.

The medical profession as a whole, working for high ideals and for greater skill and efficiency, as the years go by, looking for facts and truths in each and every field of medical science has allowed public opinion to be moulded, not in harmony with this advanced age of scientific medicine and preventive sickness.

If this state of public thought did not exist, the Owen Senate bill would have been made a law promptly, and we would now have a national bureau of health, with its chief officer coordinate with the other Cabinet officers of the Government of the United States of America.

The organized profession is now standing before the footlights of a new age in the medical world.

We are pioneers in this new era of preventive sickness and the sessions of this meeting will be an historic event.

If time permitted, I would love to trace the history of the medical profession along down through the centuries, beginning at that far-off time, when the physician's chief remedies were songs, incantations, charms and hoodooism.

Note its devotion to humanity, its brilliant successes and its scientific achievements as

civilization and enlightenment dawns on the ages.

Through the centuries, the best minds were occupied in trying to find remedies to cure people after they had become sick and then smallpox and diphtheria and scarlet fever and yellow fever and cholera raged over the countries of the world.

It was so recent as 1775 that Jenner gave to the world vaccine as a preventive for smallpox, the greatest discovery of all the ages, yet so simple. Smallpox for one hundred and thirty-seven years has been fighting a losing battle and now lies slain at our feet.

This was the dawning of the new era of preventive sickness. But it was left for Koch, only thirty years ago to roll the curtain away and look down into the invisible world, to the unaided eye, and make known to all men, the cause of consumption, the tuberculosis bacilli.

This was the real birth of the science of bacteriology and through this the bacteriologists are working out the cause of all diseases.

Knowing the cause of a disease, the nature of the germ, its life, history, much can be done to protect mankind from its deadly work.

WHAT HAS THE HEALTH BOARD DONE FOR THE COUNTY OF ADAIR?*

By U. L. TAYLOR, Columbia.

Something over twenty years ago, I received a letter from Dr. McCormack at Bowling Green, Ky., asking me to name two doctors of my county, to be associated with me in a health board for the county. I promptly complied with his request, and was appointed on the board and was made health officer, and have remained in that office ever since. When first appointed I knew scarcely anything about the duties of the office, but I went in with a determination to find out its requirements, and do whatever I was called on to do. I had an idea that if anything like smallpox were to break out in the county I would be expected to look after it, quarantine the exposed people and flag the houses and give the epidemic a kind of general supervision. This was the sum and substance of what I expected to be called on to do. But when I began studying the requirements of the law on the subject, I found that smallpox was a very small portion of the business of a health officer. Early in my official life, I found health officers were required to look after all manner of epidemics that made their appearance in the county, and as fast as I found this out, I learned not to shirk the duties thus impos-

ed upon me. I have during the whole of my official life been visiting every case of typhoid fever of which I had information, and putting the premises in the very best possible condition. If no unsanitary condition were in sight I hunted for it. If any were in sight, I began work to eradicate it. I saw that the laws of the State Board of Health required the health officer to look after the sanitary condition of the school houses of the county. I did not take second-hand information on this subject, but visited all the school houses and saw for myself. I visited all of them, about ninety in number, every year, and not only did I look after the sanitary condition, but looked after the sanitary condition of the children as well. I early came to the conclusion that the health of the county depended largely upon the health of the children in the schools. I had one hundred hand bills struck, and posted one in each school house, declaring that spitting on the floor tended to the spread of disease, and that teachers should not practice it, and should not allow their pupils to do so. In my annual rounds, I do not have to mention this matter now, because nothing of the sort is done in my county. Dr. McCormack was fortunate in the selection of a health officer for my county, in getting a man who never has tasted whiskey, and never has used its twin abomination, tobacco. Otherwise it would be like a blacksmith riding a barefooted horse or a shoe-maker letting his children go unshod, or a tinner living under a leaky board roof, or a drunkard preaching temperance, or a thief preaching honesty, or a sinner preaching sanctification. A health officer should be a healthy man. I show myself to the school children as an almost perfect specimen of physical manhood. Six feet high, straight as an Indian, weighing 175 pounds, and active at 80 years old. I tell the children that if they will live as I have lived, abstain from the use of whiskey and tobacco, never hump over, always stand upright, that many of them will live as long as I have lived, and be as active at 80 years old as I am to-day. It would be foolishness in the extreme for a man to be going around preaching the gospel of good health, to five thousand children in the county when his very looks show that he is afflicted with all the diseases known to every medical almanac. It would be foolishness for him to preach to the people that they should stand erect, when he himself is bent over like the half of a barrel hoop.

Ten or fifteen years ago, an epidemic of dysentery broke out in our county. I went on the ground and flagged every house where the disease was found, and in looking over the situation I found three large filthy ponds which I ordered drained. There was serious opposition by the owners of all of them, but

*Read before the school for Health Officers, Louisville, July 5, 8, 9, 10, 1912.

the draining was done, and the plague was stopped, but not until about ten children had perished. But there has been no epidemic of dysentery since that time.

In the last four or five years the county has been badly afflicted with diphtheria. We had a few cases in the upper part of the county, but it had generally subsided. There were a few cases not entirely well, and the county fair coming on in August, and thousands of people attending it, caught the infection, and it broke out in perhaps 20 different places. When it first made its appearance in the county, I went to all the druggists and tried to get them to order and keep in stock, a good supply of the diphtheritic antitoxin. They refused to do so, saying they were afraid of having a lot left on their hands. Up to that time I had been prejudiced against this remedy. I had been reading the *St. Louis Medical Brief*, and we had had no diphtheria in the county for quite a number of years. The accounts that I had seen in the *State Journal* had caused me to look with more favor on the antitoxin, and I was anxious to see it thoroughly tested. I accordingly took on myself the responsibility of ordering a large lot of it, and have kept it on hand ever since. When we had by the use of the antitoxin mostly eradicated the disease, there came an advertisement of a tremendous circus show to be exhibited in our town. Remembering the trouble that the fair had given us the year before, I determined to stop that circus. I accordingly called the county board of health, and by the help of the county attorney, passed an order forbidding the exhibition. There was a great kick from many of the children, and some of the men. But the best people endorsed the action of the board. I sent letters to the manager of the show, and one of them reached him at Burkesville, just two days before he was to be at Columbia. He immediately called me by telephone, and asked me to have the order rescinded. I told him I could not do it. He then proposed to have the show and exclude the children. I told him that a show of that sort would be no show at all, because the men went to shows only to take the children. The show did not come and the disease did not spread. But the antitoxin proved to be a decided success, and the doctors go as willingly to see a case of diphtheria as they do to see any other kind of a case.

Such action as was had in stopping the circus tended still further to render the health officer a very unpopular man. He is the most hated man, if he does his duty, of any other human being. If he fails to do his duty, he is cursed and abused, and if he does his duty it is worse. On this account I suggested to Dr. McCormick some time ago, that he appoint no health officer hereafter without

sending him an able-bodied fool-killer. Every thing that has been done by the health board in my county, has met with the most determined opposition of the fiscal court, and I have been us persistent in fighting that court as I have been in fighting the most deadly disease.

Really, I do believe that the fiscal courts in the State of Kentucky, have caused by their opposition to the boards of health, more deaths to result to the people than any one disease. Sometimes, however, I am constrained to think of some of our members what Roosevelt said of Taft, they mean well, but mean well feebly. One member of our court told me that he was confident that they did not pay me enough for my services, but was afraid to vote to pay me more, on account of the opposition of the people. Another one when I told him what the Court of Appeals had said about the pay of health officers, asked, "What has the Court of Appeals got to do with it?" I told him nothing, but sit up there at Frankfort, smoke fine cigars, have a good time, and make you fellows do your duty. He said the Court of Appeals had nothing whatever to do with it. Just as soon as he found out that the Court of Appeals could override the fiscal court's decisions, he resigned, and that was the most sensible and brilliant of all his official acts.

Next in importance to my fight against the fiscal court has been my fight in defense of the Vital Statistics Law. This opposition comes largely from the physicians of the county. And their opposition comes mostly because they have not received their pay. After so long a time the doctors, midwives, and grannies received vouchers for their work last year. Then they learned that their vouchers would have to be presented to the fiscal court at its October term, then if the court don't refuse to allow it, it will be paid a year from that time. But if the fiscal court in its great and mighty discretion, refuses to allow the claims, there is not one of them that will be large enough to take an appeal to the Circuit Court, and the claims will be lost, unless these doctors, midwives, grannies and registrars pool their issues, and let the claim be prosecuted by one man.

In my county the registrars are the least troublesome and the most reasonable. They want their pay, but they are not inclined to make much fuss about it. I am on very close and agreeable terms with all the registrars. I have them to furnish me with statements every six months, showing the number of deaths and births, and from what disease the deaths occurred. It has been of advantage to me in my business. In the report made to me on the first day of January, 1912, I found that one precinct in the county had twice the number of deaths from consumption, of any

other district, and yet it was by no means the largest. I inquired of the doctor doing the largest practice there as to the cause. The district is in the extreme northern part of the county, nearest to Louisville. He replied that he did not know, but as all the chronically ill were taking Charley White-Moon's medicine, that probably was the cause of it. I have been looking for some other cause for it, but up to the present have not found one. But while in that district we had ten deaths last year from consumption, up to the present this year, only two or three have been reported to me. The registrars reports for last year show that in Adair county we had 232 deaths, and 446 births, nearly two to one.

The last census shows some remarkable things. If the health officers of the adjoining counties are present, they can correct me if I am wrong. Casey county nearly the same size as Adair, in the census of 1900 had a population of 15,128, and in 1910 had gained 345. Adair county in 1900 had a population of 14,888, and in 1910 had gained 1,614. Metcalfe county in 1900 had a population of 10,000, and in 1910 had gained 400. Green county in the last decade lost about 300, but the railroad trouble accounts for that. Taylor county, on that same account had gained but little. The other counties adjoining Adair tell the same story. Now what is the cause of all this? I am vain enough, if it be vanity, to believe that it is my work as health officer that has caused the big gain in my county. I have persistently fought every epidemic that has sprung up in the county for the last 15 years. The mosquitos have so nearly been put out of commission, that I have not seen a case of old-fashioned "shakin' agur" for years. There have been but few deaths among the children in the county for quite a while. The death rate in our county for last year was only 13 to the 1000 inhabitants. And in the town of Columbia, it was only 11. Last year we had 42 deaths from consumption in the county, this year up to the first of July only seventeen have been reported.

I have reports from all the registrars in the county since the first of July, and according to these our death rate has been four less than last year, and the birth rate has been diminished by 13. This can be accounted for by the hard winter that we have just passed through. Out of 5,327 children of school age only seven have died this year. This is a good showing, and one of which I am exceedingly proud. Our deaths have been principally among old people, and they are living longer than formerly. In the town of Columbia, with a population of 1,100 only four have died this year, and two of these were over seventy years old. Only one has died this year under one year old.

But we have many foolish people in our county. Only last week a report got started that a law had been enacted prohibiting the canning of blackberries, and requiring all tomato plants to be plucked up by the roots. And as the people heard of it they became very much excited, and concluded, of course, that I was to execute the law. And many of the men cursed and swore, and defied me or any other man to come into their gardens to root up their tomato vines. Men swore now who never swore before, and men who always swore, now swore the more, and they were preparing to wreak vengeance on me or any of my agents, and there was such a mustering of old shotguns and horse pistols as had not been seen since the last Indian war. I tried to hire one young man to help me, told him I could not do all the work myself. I told him if he undertook the job, he must do it thoroughly, and to tell the people that no threat to shoot him, would terrify me at all. He then declined. I told the excited people in all seriousness that if they would do what they were required to do, that was all that would be asked of them, without ruining mad over imaginary things.

Let me say now, in conclusion, to my health officer friends, be up and doing. Try and save the lives of the people in your counties, and when the great white throne shall be set, and the remnant of days shall sit upon it, the Judge shall say, come ye blessed of my father, inherit the Kingdom prepared for you from the foundation of the world.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By A. W. WALDEN, Owingsville.

The subject assigned me, "Problems and Difficulties of the Health Officer" brings to mind what a young friend who had courted a girl with negative results had to say on the subject of love. He said that love was like a mountain that you could not get over or around. Not being able to get around this subject or over it, with your forbearance, I shall endeavor to go through it, and present a few points for your reflection. In an address to our graduating class by Professor Bevan, in Baltimore, he said, by way of encouragement, "the physician has to fight disease, death, dearth and the devil."

The labors of the health officer are confined to what is regarded as the non-remunerative branch of medicine, prophylaxis. The practical principles of prophylaxis cannot be evolved without a comprehensive knowledge of etiology. The cure and prevention of dis-

*Read before the school for Health Officers, Louisville, July 8 & 9, 1912.

case go hand in hand. The duty of the health officer is to bring into execution the adoption of such measures as will eradicate disease. The successful solution of this problem rests and abides in his ability to secure the intelligent cooperation of those with whom he has to deal. This is a foundation principle upon which we mount the ladder of success round by round.

The conflict between ignorance and science makes an awful struggle. There is no remedy for poverty. Sanitary measures are easily executed when involving intelligent, thrifty people. As to performing the duties of health officer among this class, whose confidence and cooperation we usually have, I shall merely mention that in my section, this class is largely in the majority and in my rounds on health business they give me a warm welcome. It is encouraging to know how gratefully these people receive ideas on sanitation and what is being accomplished by the investigators of the world in the preservation of health and the prevention of disease. The literature sent out to the people by our State Board of Health, through its efficient Secretary, is sowing the good seed and the people are being enlightened.

Eliminating the above class from the serious problems of the health officer, we pass into the haunts of those where the germs of disease proliferate and thrive with a prayer on our lips that God will pity the poor unfortunate victims. It is here in these overcrowded dwellings where often abides hunger, intemperance, filth, improper food, impure air and water, ignorance, poverty, social depravity, and everything that contributes to the loss of individual resistance. It is here that the health officer finds a fruitful field for his labor, problems that are difficult to solve, burdens that are too heavy to be borne. Herein lie problems, not only for the physician and health officer, but for our county judges, fiscal courts, State and Nation, our religious and benevolent institutions, and all who heed the admonition of Him who advocated feeding the hungry, clothing the naked, giving a cup of cold water to the thirsty, visiting the widows and orphans in their affliction, imparting knowledge and wisdom to the unlearned.

The health officer in order to solve the problems in his line of business which have to do with the welfare of the individual family, neighborhood, county, State, and Nation, should be a versatile genius. He should be an active and prompt business man, a good physician, a bacteriologist, a preacher, teacher, lawyer, and policeman; as in the multitude of counsel there is much wisdom. We are here from different sections of the State for mutual edification. My personal experience

as health officer may be profitable to you, yours to me, I am more anxious to hear yours than to relate mine. The unsolved problems before us are serious, important and urgent. The most serious one that confronts us is the tubercular problem. In trying to solve it when involving ignorant people who are careless in regard to their own welfare and to that of other people, as the fellow said when he tried to propose to his girl:

My heart, my brain, my legs their power seemed losing

And the perspiration from each pore came oozing."

We have to confess with humility, while much is being accomplished, we are progressing slowly in the solution of the tubercular problem. The cooperation of intelligent people can be had when they receive instruction as to the means of tubercular infection, its fatality and its prevention, but in our struggle against the disease our efforts are often opposed by ignorance, prejudice, poverty, and neglect, and in the case of a husband or wife who may have tuberculosis we urge that they occupy different beds, we forthwith receive our "extradition papers." One of the greatest difficulties in arresting the spread of disease consists in overcrowding. There are farms in my county that yield an immense profit to their owners, with large and commodious dwelling houses, expensive barns and stables, every arrangement for horses, cattle, and hogs, with tenant houses unfit for habitation. In one of these houses I attended a patient with pneumonia, with three beds in one room and ten persons to occupy the three beds. When I first saw this patient, all of the number who were grown persons, save one three year old child, were occupying these three beds in sardine fashion. I did the best I could to scatter them and give the sick man a chance to breathe. Frequently these contracted houses have open fire-places; this with the ventilation from indifferent construction affords the requisite amount of fresh air. When these houses are air tight and heated by stoves when occupied by large families, they are incubators for the germs of disease. The negroes of our towns generally occupy such quarters, which they regard as ideal. The amount of animal heat, produced in these crowded houses lessens the demand for fuel.

As a part of the combination that causes the spread of disease ignorance is an important factor. Some ignorant persons can be instructed in all that pertains to sanitation.

We have in our part of the State a peculiar variety of ignorant people. They are natural born citizens who are destitute of reason and the common powers of understanding. Being deficient in intellect they pursue a course contrary to the dictates of wisdom. They act

contrary to medical, moral, and religious wisdom. Usually they are filled with prejudice. Not being able to appeal to their reason, nothing but the cold letter of the law appeals to them. In them are found difficulties and problems for the health officers.

There was an epidemic of scarlet fever last fall and winter in one end of Bath county, between Slate Creek and Licking River, extending into Menifee county which took the combined efforts of the physicians and good citizens to arrest. We closed several schools. I made an order through Dr. Gudgeon to close the school in the iron-ore neighborhood. The trustee did not comply, and at Dr. Gudgeon's request I went out to see the gentleman and impress upon him the seriousness of the situation. I found him at a nearby country store with two of his friends. I mentioned to him that the physicians who were treating these patients agreed that they had scarlet fever and ordered that the school be closed. He remarked that the doctors are not near as smart as they think they are. One of his friends said it was not like any scarlet fever that he had ever seen. The third one chimed in with remarks equally nonsensical. My interview with these gentlemen reminded me of an incident that occurred with my wife's grandfather, Elder John Smith, an aged minister who resided in Georgetown. He was familiarly known as Raccoon John Smith. On one occasion three students of the Georgetown College agreed to play a joke on the old gentleman, by meeting him separately as they came down the street. One was to call him "Father Abraham," the second "Father Isaac," and the third "Father Jacob." The first one met him and said, "Good morning Father Abraham," the second one greeted him as "Father Isaac", he came to the third one who said "Good morning, Father Jacob." The old gentleman stopped him and said, "Friend, I am neither Abraham, Isaac, nor Jacob, I am Saul, the son of Kish, I have come to look for my father's asses and behold I have found three of them."

This convention has been an inspiration to me. It is the "biggest" missionary convention I ever attended. I have been much impressed by the great amount of scientific and statistical information, that has been handed out to us for health protection. I have been more interested by the earnestness of these broad-minded, large hearted men who have thrown the whole fiber of their being in their efforts to establish better health conditions in our State. Under the leadership of Dr. McCormack, who has zeal for himself a place so broad, so strong, so high in the hearts of every true Kentuckian, our efforts to protect the health of the people should not slacken.

As to the difficult, dangerous and disagree-

able laboratory work of Dr. South, to save the lives of afflicted people, God bless her. The final settlement with her will never be made until she reaches the city whose streets are paved with gold. It is a great achievement to pick up a brother who has fallen in a physical way, but a greater one to never let him fall.

Gentlemen, the time has arrived in the progress of this paper to say amen and quit. The subject is inexhaustible and what has been advanced, I hope will be treated as an introduction to what you may have to say. As a parting word to encourage you and to lighten your way in the noble, but difficult position you occupy as guardians of the public health, I quote from Owen Meredith's "Lucille,"

"He that lives to do good will never be unhappy—That fills the void of existence."

THE DIFFICULT PROBLEM OF BEING HEALTH OFFICER OF MET. CALFE COUNTY.*

By J. A. YATES, Edmonton.

I have been health officer since 1899. My experience during that period has been varied. The chief difficulty with a health officer in the rural districts, is the lack of education among the laity.

Outbreaks of contagious disease are not reported to the health officer promptly as they should be. Therefore almost every one in the neighborhood has been exposed. No one is willing to acknowledge his exposure but is ever ready to accuse others. So the health officer goes his round from home to home to ascertain who has been exposed.

After having quarantined many times they will steal out in his absence, giving no little annoyance to the surrounding country. The health officer's burden has been lightened in typhoid fever, pneumonia and consumption by the aid of literature furnished by the State Board of Health. The people fully realize now that these diseases are contagious. As a consequence they are on the decrease.

I believe that consumption in this county has decreased at least 50 per cent. within the last ten years. One other trouble that confronts me is the sanitary condition of the little towns scattered throughout the county. The inhabitants of these towns seem to have a vague idea of where they should dig a well or build a privy. We have had some fatal outbreaks of typhoid fever caused by improper drainage. There are a few difficulties among many others as a health officer.

*Read before the school for Health Officers, Louisville, July 8, 9, 10, 1912.

PROBLEMS OF THE HEALTH OFFICER.*

By J. L. ATKINSON, Campbellsville.

This subject covers a wide field and details would prove tiresome, so I shall be brief. My work is in a rural district so my remarks will take on somewhat the local color.

Our difficulties are such as are common to health officers everywhere except that in the small towns and country, conditions are such that our work must be a work of love and self-sacrifice, with little or no monetary consideration.

Our greatest problem is the education of the people to the value of the health conserving and life-saving work that is being done by the health department and the medical profession. Another problem is the opposition we encounter from the people whom we are serving, because they cannot believe there is not a selfish motive behind our interest in public health.

The ideal of the State Board of Health and sanitarians, that each health officer should devote all of his time to the duties of his office, is desirable but not attainable. This is true in most of the counties of the State because the fiscal courts cannot measure the work as worth the price. In my own county, and many of the counties are similar in this respect, if a competent health officer were employed for one-fourth of his time, and paid an adequate salary for that much of his time, he would be the highest salaried officer in the county. If the office paid a living salary to a competent man for his full time, the position would assume such political importance that political pull, and not competence, would determine the selection of the man.

Dr. McCormack proved by facts and figures that the health officer is not an expense but an investment. This, however, looks problematical to the people and fiscal courts in the rural communities. Facts and figures will show that considering only the monetary value of a man in the prime of life the saving of the life of one such man is worth the yearly salary of the health officer and the saving of two or three children is worth a like amount.

Consciously or unconsciously, there is an element of fatalism in the human mind in regard to health and disease. That sickness and death are entirely beyond human control is an idea that has not been wholly eradicated from the minds of the people. The divine edict that "the wages of sin is death" is no more true in the spiritual sense than that the penalty for sin against the laws of health is,

suffering, disease, and oftentimes death. Education along this line is the province of the health officer.

When a community is attacked by an epidemic the people are ready to call on the health officer to arrest the foe; but when in fancied security of health they are oblivious to the lurking foe in the stagnant pond or stream, the cesspool, the filthy back yard, the reeking alleys of our towns, the pesky housefly, the evasive flea, and other bugs and insects, carriers of infection.

The work of enforcing quarantine regulations and isolation for the control of an epidemic is evident enough to the lay mind to indicate its value to the public, but the more valuable work of prevention is not appreciated for its worth. Sickness and death must be seen face to face to make an impression on the average citizen. The sickness and death that never come because of preventive measures cannot be seen by the public hence the probability of their having occurred cannot be demonstrated.

The education of the people in the prevention of disease is the greatest work of our army of health officers at this time and until the public can be taught the value of such work it must be done for the sake of duty.

The rural health officer is usually a man of limited means, who must earn his living by his daily labor, so his work for the public health cannot be as efficient as its importance demands, but his local work is being supplemented by such a thorough educational campaign conducted by the State Board of Health that the people are being rapidly enlightened in regard to health conservation. The continuation of this educational campaign is the best solution of the present problems of the health office, in my judgment.

THE PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By E. B. McORMACK, Clinton.

The problems and difficulties of the health officer are many, the fruits of his work, under the present arrangement in Kentucky, varying and uncertain.

There is a reason why there are difficulties encountered and a remedy for a thorough and intelligent handling of any problem. We should first analyze existing conditions as making a diagnosis of a disease, then ascertain, if possible the cause, and then decide upon the remedy and apply it.

I have only been health officer of Hickman county about one and one-half years, but during that time have given this work a good deal

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

of thought, and I have arrived at this conclusion. That the one great hindrance to our work in this State is that we are working under the wrong system. The time has never been nor the circumstances will never permit of a health officer performing efficient services, and at the same time practicing medicine for a living, and I want to go on record as saying that until there is a change of the present system of work in our State, and the health officer placed on a sufficient salary to allow him to devote his entire time to health work, our efforts along this line will be in a marked degree a failure.

First, he will never be able to combine the practice of medicine and health work and at the same time get the proper cooperation of the physicians of his community.

Second, any man is going to be more efficient in the work from which he earns his livelihood, because if he fails in that particular work his income falls off. Hence, as is the case with most of the health officers of the State, they are not qualified. In a majority, if not in all, the counties of the State.

The salary of the health officer is a mere pittance as compared with what he should receive.

I like to imagine that we had an ideal arrangement of health work like this: A health officer on a salary sufficient to insure him a living in each county in the State, qualified to teach the grown people how to live and be healthy; to teach the children how to live that they would be stronger and live longer than their parents; to teach the whole people, yea, prove to them, that conservation can and should be practiced on human life.

How is it gentlemen that we have lagged in this great work so long? I do not mean to say that there has not been anything done along this line, for great strides have been made in the past few years in this particular line of work, but we are only beginning.

We, in my judgment, are in the midst of a great reform movement the Nation over. Then let us as guardians of the lives and health of the people not lag behind, but like brave men shoulder the load, and with new and determined zeal inaugurate into our State the ideal system of health work. Namely: A health officer in each county in the State on a reasonable salary to allow him to make out of himself an ideal health officer—one qualified and ever ready to solve the problems that may arise which are calculated to prevent sanitary conditions of his community. Thus allowing him to be to the people an ideal health officer, but some of you may say that this can not be accomplished at once. I believe that with a concerted effort of the 2,000 physicians of Kentucky to bring it about it can be done, and I for one, believe that here is the place and

now is the time to organize for such a movement. I feel it a duty we owe to our people to do this now. It may seem that I have not adhered to my subject very closely as I suppose the problems and difficulties of health officer under the present system of work should have been discussed, but as I have very little faith in the amount of good that can be done under the present system, I feel I must add my support to the idea I have suggested.

We may expect to find obstacles in the path of progress, but the main one in this great fight is ignorance—that is the one great hindrance to this work, but we should be only too glad to make the greatest possible effort to enlighten the ignorant and convert the skeptical to the greatest work of the present age—"Conservation of human life."

Syphilitic Disease of the Aorta.—Goldscheider states that the prevalence of involvement of the aorta is still underestimated. During the last two years he has encountered ninety-seven cases in his private practice and forty-nine in the polyclinic. His experience confirms anew the favorable influence of specific treatment on the syphilitic affection of the walls of the aorta. Small aneurysms may retrogress entirely and medium-sized ones to a certain extent, but little effect can be anticipated in the cases of very large aneurysms; here benefit is exceptional. Iodid treatment alone never displayed any appreciable influence on syphilitic aneurysm of the aorta in his experience. General hygiene is especially important; in two of his cases carelessness in this line on the part of the patients interrupted the progressing improvement and put the patients back in their old condition. He is confident that by repeating the course of specific treatment from time to time the patient's life can be materially lengthened if he takes the proper precautions.

Origin of Gall-Stones.—Hofbauer argues to prove that the erect position of man is responsible for the conditions which favor cholelithiasis, the flow of bile not being so free as in four-footed animals. Human beings must make an effort to improve conditions in this respect, and he says this can be accomplished by training the diaphragm to wider excursions. He advocates deep abdominal breathing as a kind of automassage of the liver and bile ducts. The abdomen should be drawn in during expiration, not during inspiration. The abdominal musculature should be made to aid in expelling the breath. This forces the contents of the abdomen up toward and against the relaxed diaphragm and vice versa.

THE FORUM

Old Drennon Distillery, H. D. Edgars, Sole Distributor, Louisville, Ky., Season, 1912.—Dear Sir: The Kentucky laws permit you to receive whiskey shipments in 5 gallons or less in unbroken packages.

There are a number of people in your neighborhood who would like to receive goods but cannot order within the state as the laws prevent shipments to any but licensed doctors or druggists.

If you will permit those who wish to order to have goods shipped to you, without expense to you, it will be an accommodation to both of us.

This in no way violates the state laws, as you will see from the enclosed clipping, which quotes the law on this point.

Will you kindly write on the back of this letter a few names of friends to whom I may send my price list, and allow me to ship the goods to you, where the package can be called for?

We can not afford to pay a commission; I do not know if this would be legal, but I will be glad to give you a free gallon for every ten I ship to you, to reward you for the trouble in handling.

The enclosed card explains my plan of giving a free gallon.

Write on the back of this letter only the names of those who may mail me an order in your name and have the goods go to you—they can call at your place for the package, or get it in your name, at the express office.

I will handle the shipments in such a way as to cause you no trouble, and you will receive a gallon of my very finest Old Drennon for your kindness, every time I receive orders for 10 gallons—you keep track of the orders on the card, and return it to me.

Should you wish to send me an order for Old Drennon, I will present you with an extra full pint of very fine stock, to pay for the names you write on the back of this letter.

Old Drennon is a very choice pure, straight whiskey, and is used in general practice of physicians.

Please write me.

Yours very truly,

H. D. EDGARS.

Return this letter with names on back, if you will also order, I give you an extra Free Pint.

August 10, 1912.

Mr. H. D. Edgars, Louisville, Ky.—Sir: I realize that it is perhaps not worth while and yet I desire to devote sufficient time to your offensive letter of recent date to resent the insult which it implies.

As I have no intention of engaging in the whiskey business, I do not see what right you had to presume that I would be interested in your bootlegging proposition, even though you generously offer to give me a small package in payment for my services. Your construction of the law would be interesting and amusing if the proposition you make to me, and I presume generally to the physicians of the State were not so insulting. It becomes quite clear that your estimate of the character of the doctors generally, differs very much from that of the law makers who made an exception in their case and permitted them to order whiskey presumably for a medicinal purpose.

Since you doubtless find it profitable to deal with the weaker element of the medical profession, I wonder that you do not branch out a little and include the illegal sale and distribution of cocaine, morphine and some of the other deadly poisons which doctors are permitted to order and which unfortunate human beings often want. You must of course admit that such traffic would be quite as honorable and as respectable as that which you so brazenly invite me to share with you.

As for sending you a list of my friends I must say that unless your whiskey is vastly superior to your ethics, I have no friends for whom I care so little as to expose them to either, and I feel that it would be rather a cowardly way of getting even with my enemies.

Since you have taken the liberty of opening this correspondence may I ask you in simple fairness to advise me just how you procured my name and what justification if any you have for presuming that I would be interested in such a scheme.

Yours truly,

THOMAS C. HOLLOWAY.

(Copy).

Röntgenotherapy of Goiter.—Question-blanks were sent to a number of German clinicians for their experiences in this line. They have no favorable reports to make on roentgenotherapy for simple goiter and generally advise against it, but for exophthalmic goiter the majority regard it as fully equal to any other therapeutic method. The thyroid subsides under it, and likewise the specific Basedow symptoms, the exophthalmos, tachycardia, other symptoms on the part of the heart and nervous system, while the general health improves and the patients gain in weight. Krause urges routine histologic study of thyroids when they are removed or inspected at necropsy after exposures to the Röntgen rays.

WEARING GLASSES.

By DUDLEY S. REYNOLDS, Louisville.

Whilst it is a matter of history that spectacles were invented by Friar Bacon, and first used by him in 1283, and that, several of his associates and personal friends used them afterward, no attempt was made to adapt them to the uses of young people for more than five hundred years.

John Kepler, in 1601, discussed the value of concave lenses for correcting myopia, and taught the world a simple and easy method of making lenses.

Occasionally we read of a person who was near-sighted, and who aided his vision for both near and distant objects by the use of concave lenses.

The first hint of astigmatism as an optical defect in the eye is contained in Dr. Thomas Young's essay, published in the Philosophical Transactions for 1793. The astronomer, Mr. Airy, in a communication to the Philosophical Society at Cambridge in 1827, described compound myopic astigmatism in his own eye. Mr. Stokes, in a report to the British Association for the Advancement of Science, in 1849, described the use of cylindrical lenses in determining the degree of astigmatism; while Dr. Goode had reported a year previously, some cases of astigmatism.

Mr. Wells, the astronomer, in 1811, reported in the Philosophical Transactions his discovery of hypermetropia in his own eyes. On November 19, 1812, Mr. James Ware presented to the Royal Society some observations relative to near and distant sight for different persons, for the first time inviting atten-

tion to the fact that, "young persons sometimes have such a disproportionate convexity of the cornea, or crystalline, or of both to their distance from retina, that a glass of considerable convexity is required to enable them to see distinctly both near and distant objects."

With other observations following in rather rapid succession, Dr. Wm. Kitchiner, of London, published a little book entitled "The Economy of the Eyes," which was reprinted in this country by Wells & Lilly, and E. Littell, of Boston, and Philadelphia, in 1824. Dr. Kitchiner says, "Everybody is in want of information as to how to choose spectacles, and nobody has given it;" therefore, he endeavors to render it easily attainable, as it is universally desirable. The sight cannot be perfectly suited unless each eye negotiate for itself. In discussing the question of age, he says, "the common opinion that there is an invariable rule that a certain glass is calculated for a certain age is a vulgar error," and that, "no rule has more exceptions than this." He discusses such glasses as were being advertised at that time, under the name of "Sympathetic Pebbles," which were warranted "to alter as the sight alters." Says he, "A single-glass, set in a smart ring, is often used by trinket-fanciers merely for fashion's sake, by folks who have not the least defect in their sight, and are not aware of the mischievous consequences of such irritation; this pernicious plaything will most assuredly, in a very few years, bring on an imperfect vision in one or both eyes." This no doubt, is the origin of the monocle, which English snobs and cockneys still use in public places.

It is not an uncommon thing to find in the advertising pages of the newspapers an ac-

count of "X-ray glasses," "glasses made of diamond dust," "magnetic glasses," and many other kinds of impossible lenses.

About the time Kitchiner's book appeared the elder Sichel, of Paris, published a guide to the use of spectacles, which became very popular. The astronomers and mathematicians may, however, fairly be credited with the discovery and elaboration of those principles of science upon which all our knowledge of spectacles is based.

The subject of refraction and accommodation of the eye was first brought to the notice of the medical profession in an elaborate treatise by Prof. Donders, of Utrecht, in his immortal essay written for the New Sydenham Society of London, and published in 1864. Donders defined principles, and established rules of conduct in the determination of errors of refraction in the human eye, which are now recognized and followed throughout the civilized world.

Passing over the question of plain, spherical, cylindrical, and mixed aberrations of refraction, the general profession of medicine must recognize the modifying influences of certain diseases, and be able to determine who may and who may not with advantage wear spectacles. If no contraindicating disease exists in the eye of the person having an error of refraction, the question of the correcting lenses, and their proper adjustment remains to be determined. An intimate knowledge of the functions of the normal eye can alone enable one to comprehend abnormal conditions. Some knowledge of the principles of therapeutics is necessary to enable one to suspend the function of accommodation in the eye, in order that, its refracting media shall be in a state of quiescence while the test of refraction is being made.
